Mr. James Cronin, formerly managing director of the St. Eugene and associates, have disposed of the Canadian Girl and the Yankee Girl claims in the Ymir district to H. L. Rogers, of Spokane, representing eastern capital. The consideration is $40,000. Work has been commenced on the property, which is a silver-lead prospect of merit and appears to have a promising future.

The Ymir Mining Company is going to spend $30,000 in development work and improvements about the Premier mine of Ymir district. Having recovered the main ore body the outlook for the Ymir is better than it has been for four or five years.

A visitor to Nelson this week says that a record quantity of gold is now passing through the Assay Office at Vancouver. The staff is working overtime and on holidays, and a recent shipment of gold received from the north was valued at over a quarter of a million dollars. It is presumed that the recent trouble at the assay office in Seattle has diverted some of the trade that used to go to that institution to the Vancouver office.

At the Vancouver mine, Slocan, operated by the Le Roi 2, Limited, they are installing the first half of a twenty-drill Rand compressor.

The Blue Bell mill is making concentrates at the rate of a barge load per week. The handling of the concentrates is made an economical process by dumping them directly from the cars to the barge in bulk. Just now the zinc in the Blue Bell ore is not being saved, but negotiations are under way for the installation of a magnetic plant to accomplish this. The Hewitt Mining Company have organized. Their head office is Wilmington, Del., and they will have a branch at Nelson. The Hewitt Company are successfully operating the Hewitt and other properties at Silverton.

The International Coal and Coke Company will deduct three-quarters of 1 per cent. from their regular quarterly dividend of 2 per cent., payable August 1st, which is to be applied to their outstanding bonded indebtedness of $200,000, so the shareholders will only receive a dividend of 1¼ per cent. this time. The company is steadily producing 2,000 tons of coal per day.

GENERAL MINING NEWS.

NOVA SCOTIA.

[**Editor's Note.**—The following is a press despatch. It will come as exceedingly bad news to those interested in Nova Scotia gold mines. Until further particulars appear it is impossible to size up the situation. It may be stated, however, that the financial difficulty that has crippled the company, does not indicate that the mine is exhausted. In our next issue we intend to demonstrate that this is an excellent opportunity for the Government of Nova Scotia to step in and put the mine once again in operation.]

Halifax.—The Boston Richardson mine at Goldboro, the largest gold mine in Nova Scotia, has gone into liquidation and is now in the hands of a receiver. An application was made to the Supreme Court to-day for an order appointing a receiver, and after hearing counsel, the judge to whom the application was made granted an order appointing the Eastern Trust Company. An expert, representing the receiver, will leave to-day for the mine, where he will make a thorough and complete investigation of the mine and its potentialities. His report will be submitted to the court in order that further instructions may be given to the receiver.

The collapse of the Richardson mine means heavy financial loss to many in Halifax, but the greater part of the mortgage bonds were held in Boston. At the present time there is about $52,000 owing by the company on current account. Besides this there is $59,000 owing on first mortgage bonds.

Of a total capitalization of over half a million, about $350,000 of consolidated mortgage bonds have been issued and sold, and those will rank after the mortgage bonds. Practically the whole of the first mortgage bonds are held in Halifax. The consolidated mortgage bonds are almost entirely held in Boston. Probably the largest holder is Franklyn Playter, the president of the company, who has lost his private fortune backing runing operations at Goldboro. Another large loser is Mr. Wallace, a prominent banker and shoe manufacturer in New Hampshire. He is a close personal friend of President Playter and invested very largely in the mine, and his loss will be heavy. Playter is president of the United Zinc Company of America.

Glace Bay.—The Dominion Coal Company's output for July was 368,000, which breaks all previous records. The next largest, 350,000, was raised during October, 1906. But for some accidents the July output would have been good for many thousand tons larger.

Glace Bay.—Through the fall of a cage at No. 9 colliery of the Dominion Coal Company's mines, work was delayed for a few days.

Springhill.—In No. 3 slope of the Cumberland Coal Company's collieries, Percy Jordan, a young negro, was crushed between the boxes and fatally injured.

ONTARIO.

Belleville.—Substantial gold discoveries are reported from the township of Elzevir, Hastings county.

Madoc.—The talc grinding mill, recently put in operation here, has sufficient orders to keep it moving for some time to come.

Cobalt.—Three miners, natives of Cape Breton, Foley, McDonald and Gillies, were suffocated by gas in French's mine at Elk Lake, on August 1st.

Cobalt.—Manager McNaughton has installed a crusher at the Tretheway. Additional machinery is to be installed. During July the Tretheway shipped 400,070 pounds of ore, seven carloads. The rumors of a coming dividend still persevere.

La Rose mine shipped more ore during July than did any other Cobalt mine. Its record was 18 cars, or 1,028,880 pounds. Nipissing came next with 13 cars, or 727,707 pounds, and O'Brien 11 cars, or 725,697 pounds.

The shipments of the camp for the month were heavier than ever before. A total of 2,584 tons was reached. This is a large increase over any previous monthly output.

Larder Lake.—While the limits of the pay zone of the Harris-Maxwell mine have not yet been determined, rich ore has been encountered in the drift, which is being driven in just above water level. A quantity of specimen gold ore has been obtained, some of which has got into dishonest hands and has been used to sell stock in other properties.

Port Arthur.—New machinery is en route to the Beaver mine. A carload of silver ore has just been shipped.

Haileybury.—The new townsite, "Sixty-Six," in South Lorrain, is being cleared and laid out. From its situation it forms an advantageous base of supplies for the new mines of the district.

Wabigoon.—Near the junction of the Lake Superior branch with the main line of the Grand Trunk Pacific, on the north shore of Vermilion Lake, is situated the mine of the Northern Pyrites Company. The shaft is down 220 feet, and a considerable amount of cross-cutting and drifting has been done.

Sudbury.—The Mond Nickel Company is developing the Garson mine rapidly. Ore is being purchased from outside producers.

Port Arthur.—Existence of a large and valuable deposit of nickel north of the Transcontinental Railway, and 100 miles west of here, is reported by T. H. Crowley, of Peterboro, a prospector, who has a long experience in all parts of Ontario. Crowley arrived in the city recently, en route home, after spending several weeks in that country, and showed a number of excellent samples. One contained both silver and free gold and he said lots of it was to be found north of Wabigoon and Sturgeon lakes. He also claimed to have uncovered at a point some distance northeast, a vein of almost pure nickel, and expressed the opinion that a large ring of it would be found to exist there.

BRITISH COLUMBIA.

Fernie.—A few days before the fire the Crow's Nest Pass Coal Company commenced the construction of fifty additional coke ovens, twenty-eight at Fernie, twenty-two at Michel.

Fernie. Twenty-four miners were entombed in the C. N. P. Coal Company's No. 2 mine, Coal Creek on July 31st at 8 a.m. Prompt measures were taken and all of the miners were rescued.

Fernie, Aug. 5.—The work of rebuilding the town of Fernie has already commenced. The new C. P. R. station is almost ready for occupation. At date of writing every man, woman and child has been provided with shelter.

Phoenix.—Work is to be resumed at the Snowshoe mine. Shipments amounting to 125,000 tons of ore were made up to the middle of last November, when the mine was closed. The reopening of the Snowshoe will mean the blowing in of another copper furnace at Trail.

Rossland.—The Sunset mine has joined the list of shippers.

Phoenix.—The Granby Consolidated has purchased the Golden Eagle claim. The reported price was $12,000.

Nelson.—The first shipment of zinc ore has been sent to the new zinc smelter.

Kaslo.—A carload of zinc ore from the Hewitt mine is being put through the plant of the Kootenay Ore Company here.

Mr. Louis Pratt is arranging to open up the Last Chance mine at Sandon.

The Silver Cup mine at Ferguson is shipping steadily. Sixty men are employed. Four stopes are being worked.

YUKON.

Dawson.—A ledge of copper ore has been discovered on Williams' Creek, 230 miles above Dawson. The vein matter is quartz and the copper-bearing minerals bornite, malachite and chalcopyrite.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The statement submitted to the shareholders of the Glamorgan Colliery Company at a recent meeting showed 40 per cent. profits on the year's transactions, in addition to paying arrears of dividends on preference stock. Another striking record of a South Wales coal company is that of the International which, during a period of ten years, has realized profits amounting to 20 per cent. per annum.

Of the total output of collieries in Great Britain last year, amounting to 267,828,000 tons, only 12,877,000 tons, or less than 5 per cent. were hewn by machinery. The use of coal-cutting machines, however, is rapidly increasing, the quantity cut in this manner showing an increase of 26 per cent. over the like output in 1906.

FRANCE.

The quantity of bauxite exported from France in 1907 was 110,915 tons, of the value of £94,000. The chief sources of supply are a few miles east of Marseilles, the deposits being the most important in the world.

RUSSIA.

The gold discovery on the lower Amascov, Siberia, from preliminary investigations is estimated to contain 230 poods, or 121,151 ounces of gold. Pits are being dug and working will be begun immediately.

NORWAY.

A shipping duty of 25 öre per ton has been placed upon all ore exported from Norway.

GERMANY.

The Bavarian Government is acquiring the Stockheim collieries, paying therefor 2,500,000 marks, and an annual rental based on a sliding scale, increasing with the output.

An investigation is being carried out by a special committee of the German Gas and Water Association on the subject of gas coals. So far twenty-eight different kinds of coal have been tested.

AUSTRALASIA.

Two seams of good coal, respectively 7 feet and 4 feet 6 inches thick, having been found on the property of the Mount Morgan Gold Mining Company, Queensland, a mine will be opened.

The Northern Federation of Miners, New South Wales, have repudiated the New Industrial Disputes Act, and declared their intention of reverting to the strike system. As strikes are illegal under the act serious complications may result.

The Queensland Government has devoted £50,000 to the encouragement of the mining industry. The Government geologist is visiting the principal mining fields of the State to ascertain how the money can best be applied.

SOUTH AFRICA.

The De Beers diamond mine at Kimberley, the largest in the group, was closed down July 31st in pursurance with the policy of the company to restrict the output and reduce expenditures until the market revives. The syndicate which markets the De Beers output have on hand a stock of uncut stones worth nearly $10,000,000.

The report of the Secretary of Mines for Rhodesia for 1907 notes steady progress in the gold mining industry, the output being 612,052 ounces valued at £2,178,886. The total crushing power in operation was equivalent to 1,488 stamps and five tube mills. The diamond yield was 4,363 carats, value £20,193.

UNITED STATES.

On July 24th the new smelter of the Tintic Smelting Company, built at a cost of about $300,000, in the Tintic mining district, Utah, was blown in.

High grading, which is said to prevail to a greater extent at Goldfield, Nev., than in any other mining camp, resulted in the fatal wounding of one of the offenders at the Mohawk

mine, who refused to surrender when caught in the act. Another was arrested.

Gold dredging is being extensively undertaken in Calaveras county, Cal., to secure the tailings of the old-time miners, which contain much gold.

Plans are practically complete for the construction of a railroad into the Yerington copper district, Nevada, in connection with the Harriman railroad system.

The first cargo of 12,000 tons of iron ore arrived at the new plant of the United States Steel Corporation, at Gary, Ind., on July 23rd.

MEXICO.

By a Mexican law recently promulgated machinery imported into Mexico by mining syndicates and metallurgical establishments for refining the precious metals will continue exempt from import duty until June 30, 1909.

The proposed anti-foreign mining legislation has been referred by the Cabinet to President Diaz, who is given authority to accept and enforce or to reject the measure.

CHILI.

The consumption of coal has increased very rapidly in the last five years, the gain in that period amounting to nearly 300 per cent. An effort is being made to develop the very extensive coal fields of the Province of Aranco, south of Coronel.

COMPANY NOTES.

The Tretheway Silver-Cobalt Mine, Limited, has declared a 5 per cent. interim dividend, payable on September 1, 1908.

The Mond Nickel Company has made remarkable progress recently and further evidence of its prosperity is given by the dividend declared last month. The distribution on the ordinary shares, which a year ago was 12½ per cent. is increased this time to 15 per cent., while the deferred shareholders will receive 48, as against 33 per cent. At the same time £25,000 is placed to reserve, as compared with £20,000, and the balance carried forward is £11,600 larger than last year, amounting to £29,900. Considering that the first dividend on the ordinary shares were declared only three years ago, and that two years before then the preference interest was not fully earned, the progress made since the initial difficulties were overcome has been astonishingly rapid.

The high price of copper has been of great help during the past financial year, but the low price now ruling must reduce the profits. The Mond process converts all of the copper into sulphate of copper, which is largely used for the manufacture of paris green by mixing with arsenic. It is claimed for the Mond nickel that it is the purest of any offered to consumers.

The directors of the Crow's Nest Pass Coal Company have authorized the rebuilding of the parts of the plant destroyed by fire at Fernie. Although no fixed appropriation was made, it is estimated that the net cost to the company of the rebuilding and refitting will be in the neighborhood of $50,000. The fire destroyed the hospital, and did considerable damage to the coke oven plant and other equipment, the total loss being placed at about $200,000. There was about $150,000 insurance held on the plant. The work of rebuilding will be started immediately.

COBALT DIVIDENDS.

July dividend payers are as follows:

Nipissing (regular 3 per cent. quarterly)	$180,000.00
McKinley-Darragh (interim 3 per cent. and 2 per cent. bonus)	112,346.85
Kerr Lake (regular 2 per cent. and regular 1 per cent. bonus)	90,000.00
Crown Reserve (half-yearly 4 per cent)	80,000.00
Temiskaming (regular 3 per cent. quarterly)	75,000.00
Temiskaming & Hudson Bay ($6 per share on 7,700 shares)	46,200.00
Buffalo (regular 3 per cent. quarterly)	27,000.00
City of Cobalt (interim 3 per cent. and 2 per cent. bonus)	25,000.00
Grand total from July 1st to 20th	$635,546.85

STATISTICS AND RETURNS.

NOVA SCOTIA COAL MINES.

Nova Scotia Steel and Coal Company—

Shipments July, 1908	72,740
Shipments, July, 1907	82,605

Decrease July, 1908	12,473
Shipments 7 months, 1908	222,865
Shipments 7 months, 1907	213,413
Increase 7 months, 1908	9,452

DOMINION COAL COMPANY'S OUTPUT.

The July output of the Dominion Coal Company is in the vicinity of 368,000 tons. The company, for the seven months of the year, shows an output of 2,292,000 tons, or 317,000 tons ahead of a year ago. The output in detail follows:

	Tons, 1908.	Tons, 1907.
January	314,108	252,248
February	285,649	225,988
March	346,529	212,831
April	298,745	316,384
May	332,588	327,269
June	347,000	319,000
July	368,000	321,000
Total tons	2,292,619	1,974,720

CROW'S NEST PASS OUTPUT.

The output of the Crow's Nest Pass Coal Company for the week ended August 1st was 24,711 tons, a daily average of 4,118 tons. For the corresponding week of last year the output was 21,677 tons, a daily average of 3,613 tons.

Sydney, August 4.—July was another record breaker for output from the collieries of the Nova Scotia Steel and Coal Company, being over three thousand tons greater than the previous month. The figures follow:

No. 1	21,153
No. 2	3,097
No. 3	24,495
No. 3	1,337
No. 4	9,236
Total	59,318

THE DOMINION STEEL OUTPUT FOR JULY.

The furnaces were idle the first five days of July for holiday and other causes. The balance of the month produced 22,080 tons of steel, from which was rolled 16,405 tons of rails, 2,503 tons of rods, besides considerable tonnage of steel blooms and billets for the market. Shipments aggregated 23,332 tons.

Toronto.—Shipment returns from the Cobalt camp for the week ending Saturday, August 1st, were a little belated this week. They totalled 1,021,331 pounds of ore or 510 tons, considerably less than the previous week, which amounted to 743 tons and was a record. Ten mines shipped for the year to date 22,569,053 pounds, or 11,234 tons. Shipments for the week and year to date are:

Reco	21	185
Keystone	8	50
Little Robert	1	1
Other mines	.....	17,990
Total	1,647	56,807

The total shipments for the past week were 45,960 tons, and for the year to date 963,537 tons.

Smelter Receipts.

Grand Forks	20,261	624,566
Greenwood	14,052	106,036
Boundary Falls	5,115	16,788
Trail	6,545	164,430
Northport (Le Roi)	1,576	48,665

The total smelter receipts for the past week were 47,549 tons, and for the year to date 966,205 tons.

Following is the report of the manager of the Le Roi mine for the month of June, as cabled to the London office of the company:

"Shipped from the mine to Northport during the past month 5,100 tons, containing 2,429 ounces gold, 2,450 ounces silver and 101,000 pounds copper. Expenditure on development work during the month, $9,000."

Following is the report of the manager of the Le Roi Two for the month of June, as cabled to the London office of the company:

"Shipped 2,390 tons. The net receipts are $48,626 (£10,026), being payment for 2,352 tons shipped, and $1,067 (£220), being payment for 76 tons concentrates shipped; in all $49,693 (£10,246)."

Following are the figures of German consumption of foreign copper for the months January-May, 1908:

	Tons.
Imports of copper	72,247
Exports of copper	3,354
Consumptio nof copper	68,893

As compared with consumption during the same period in 1907 of 47,979 tons.

Of the above quantity 67,155 tons were imported from the United States.—Figures from L. Vogelstein & Co.

The following were the figures of German consumption of foreign copper for the months January-June, 1908:

	Tons.
Imports of copper	82,968
Exports of copper	3,878
Consumption of copper	79,090

As against consumption during the same period in 1907 of 55,507 tons.

Of this quantity 75,759 tons were imported from the United States.—L. Volegstein & Co.

MARKET REPORTS.

Coke.

August 11.—Connellsville coke, f.o.b. ovens—

Furnace coke, prompt, $1.60.

Foundry coke, prompt, $2.00.

Other Metals.

August 11

Tin, Straits, 30.75 cents.

Copper, prime lake, 13.875 to 14 cents.

Lake, arsenical brands, 13.85 to 13.95 cents.

Electrolytic copper, 13.875 cents.

Sheet copper, 18 cents.

Copper wire, 15.25 cents.

Lead, 4.60 cents.

Spelter, 4.75 cents.

Sheet zinc, 7.50 cents.

Antimony, Cookson's, 8.25 to 8.375 cents.

Aluminium, 32 cents.

Nickel, 45 to 47 cents.

Platinum, $23.50 per ounce.

Bismuth, $1.75 per pound.

Quicksilver, $42.50 per 75-pound flask.

MARKET NOTES.

Immediate advances in the price of tin and slow gains in copper prices are predicted by market authorities. The general improvement in the metals market is likely to continue.

Antimony firm and shows signs of strengthening.

Pig iron is low but firm.

Coke production is increasing rapidly.

MAP OF NOVA SCOTIA.

The Boston-Richardson Mine, temporarily closed owing to financial difficulties, is situated on the Atlantic Coast of Nova Scotia. (See General Mining News.)

NEW YORK, 16 Exchange Place
LONDON, England: 2 Lombard St., E.C.

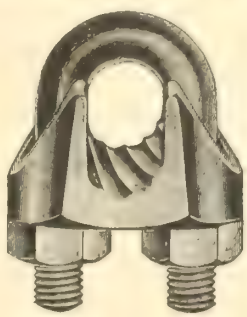
Branches at COBALT and LATCHFORD, in the silver mining camp of New Ontario.

Amatite ROOFING

Amatite has one distinction which makes it stand out above all others. **It has a real mineral surface.**

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather.

This mineral surface is embedded in a layer of Pitch, **the greatest known waterproofing material.** Beneath this in turn are two layers of the best grade of felt—cemented together by more Pitch, making the whole a roofing that is **absolutely fireproof.**



No other ready roofing can compare with this mineral-surfaced, waterproof, weather-proof, durable roof. That's what we say—**Don't buy your roofing until you have seen Amatite.**

Free Sample and Booklet

Send for Free Booklet and Sample to-day. It will pay you to get acquainted with Amatite. Address nearest office.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

University of Toronto

FACULTY OF APPLIED SCIENCE AND ENGINEERING

Courses in

1. Civil Engineering.
2. Mining Engineering.
3. Mechanical and Electrical Engineering.
4. Architecture.
5. Analytical and Applied Chemistry.
6. Chemical Engineering.

Diploma granted at the end of three years. B. A. Sc. at the end of one additional year.

Professional Degrees:

Civil Engineer (C. E.)
Mining Engineer (M. E.)
Mechanical Engineer (M. E.)
Electrical Engineer (E. E.)
Chemical Engineer (C.E.)

For Calendar and other information apply to the Secretary

A. T. LAING.

School of Mining

A COLLEGE OF APPLIED SCIENCE

AFFILIATED TO QUEEN'S UNIVERSITY

KINGSTON - ONTARIO

1. Four Years' Course for a Degree (B.Sc.)
2. Three Years' Course for a Diploma in
   - (a) Mining Engineering.
   - (b) Chemistry and Mineralogy.
   - (c) Mineralogy and Geology.
   - (d) Chemical Engineering.
   - (e) Civil Engineering.
   - (f) Electrical Engineering.
   - (g) Mechanical Engineering.
   - (h) Biology and Public Health.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

JUDICIAL SALE

of all Assets of the Copper Mining and Smelting Company of Ontario, Limited in Liquidation.

Sealed tenders will be received, addressed to His Honor F. W. Johnson, Local Master, Sault Ste. Marie, Ontario, and marked "Tenders in THE COPPER MINING AND SMELTING COMPANY of Ontario, Limited, Liquidation," up to twelve o'clock noon on the Fifteenth day of September, 1908, for the purchase of all the assets of the said Company now in the possession and control of the Liquidators, which assets consist of the valuable Mine and Mining Property situated in the Town of Bruce Mines in the District of Algoma and Province of Ontario, on the North shore of Lake Huron (where there is a good harbour and shipping facilities) with machinery, buildings, plant and full equipment situated on the premises, and wharfage, railway tracks and sidings.

Tenders will be received for the entire property or for any of the following parcels:

PARCEL 1

Mine, Mining Rights, Buildings, Machinery, Plant, Concentrating Mill, Railway Track and Sidings, Coal Dock, Skimpings, Slimes and Ore already won. There are two principal working shafts some 500 feet in depth, which have been in full operation until recently. The property consists of all the mineral rights in two grants or locations, embracing an area of some 20 square miles (with the exception of 116 acres already disposed of), also the surface rights of about 665 acres of said lands (of which 300 acres are within the limits of the Town of Bruce Mines).

Bruce Mines Station of the Canadian Pacific Railway, situated on the property, is 135 miles from Sudbury and 37 miles from Sault Ste. Marie. The Bruce Mines and Algoma Railway here crosses and runs down to the Lake, having a station and sidings convenient to the mines.

THE BUILDINGS, adapted to large operations, are in good condition, and consist of machine shop, fully equipped, blacksmith's shop, store houses, oil house and boiler houses, two power houses, mill offices, Manager's and Mill Superintendent's houses, boarding house, ice house, stable and dynamite magazine.

THE MACHINERY AND PLANT, which are in good running order, have an inventory valuation of $96,500.00. The concentrating mill, situated on the Lake front, has a capacity of 250 tons per day and pumping plant of 60,000 gallons per hour. Its construction and equipment cost $130,000.00. The Electric Light plant has a capacity of 500 lights. One and one half miles of Railway Track (with sidings) connect the mine proper with the Concentrating Mill and Coal Dock, where vessels drawing 16 feet can load and unload.

THE SKIMPINGS, estimated at 120,000 tons, are useful for fluxing purposes in nickel smelters, and for the manufacture of artificial stone. A separate tender for these skimpings will be considered. The ore already won and in the stopes is estimated at 9,000 tons. Considerable development work has also been done on the property exposing a large body of ore.

PARCEL 2

TOWN AND PARK LOTS, containing about 300 acres within the town limits, sub-divided into over 100 convenient building lots.

WATER LOTS, situated in front of the Concentrating Mill and adjoining the coal dock.

ISLANDS: "French," "McCoys," "Bruce," "Rat," "Mouse," having in all an estimated area of 75 acres, with some suitable lumber-mill sites.

PARCEL 3

RANGE LOTS, consisting of about 365 acres in the Township of Plummer Additional.

PARCEL 4

WHARF AND WAREHOUSES, conveniently situated, adjoining the Government Dock, with 16 feet depth of water.

Tenders for separate lots and islands mentioned in parcels 2 and 3 will be considered.

The principal workings are being kept free of water and will be open for examination by intending purchasers. Full descriptions and particulars of the real estate and full details, inventories, etc., of the plant, machinery and other assets of the Company can be obtained upon application to the Liquidators - T. Hayes Sheen, Jnr., at Bruce Mines, Ont., or R. C. Jennings, 18 Toronto Street, Toronto. A full inspection of all the property may be had at any time.

As to the real estate, it is understood that the foregoing description is only a general description and the areas given are only approximate and the purchaser is to satisfy himself as to the quantity of land and the title of the Company thereto and shall search the title at his own expense and the liquidators will not be required to furnish any abstract of title or to produce any title deeds other than those in their possession.

TERMS OF SALE: 10 per cent. cash; 40 per cent. within 30 days, and balance within 60 days, with interest at 7 per cent, secured to the satisfaction of the Liquidators. **The tenders must be accompanied by a marked cheque, payable to the Liquidators for 10 per cent of the amount of tender, which will be returned if tender is not accepted.**

The highest or any tender not necessarily accepted.

The other conditions of sale are the standing conditions of sale of the Court as far as applicable.

For further particulars and conditions of sale, application may be made to either of the above-named Liquidators or their Solicitors.

DATED at Sault Ste. Marie this Third day of July, A.D., 1908.

F. W. JOHNSON, Local Master.

HEARST, McKAY & DARLING, Sault Ste. Marie, Ont.
Solicitors for Liquidators.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

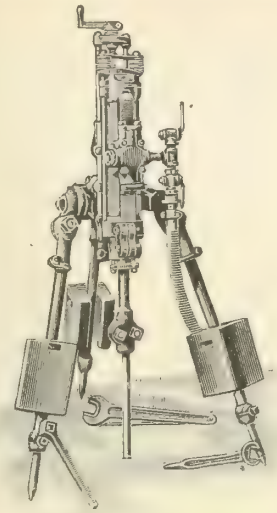
RAND AIR COMPRESSORS

EFFICIENT AND ECONOMICAL



Complicated mechanism in air compressor design is regarded as an element of weakness and it is the elimination of such non-essentials that has produced the up-to-date RAND Machine; a machine which operates with the minimum of attention and repairs.

Our Catalogs describe Rand Compressor Construction.

TORONTO, ONT. WILLIAMS & WILSON, MONTREAL, QUE. WINNIPEG, MAN, VANCOUVER, B.C.

A VARIABLE DEMAND

for air power, in mining service, may be met with economy and reliability by the use of Sullivan Duplex Self-oiling Air Compressors.

The steam driven machines of this type (illustrated above) are able to start without attention, thus proportioning the power used to the air supply required. The steam distribution is controlled by a hand-adjusted cut-off.

The main bearings, crossheads and eccentrics are housed, to exclude grit and dust and are oiled automatically from central tanks.

The use of two-stage air cylinders, with large water jackets and an intercooler, secures high air efficiency.

They are built in 5 styles (3 steam and 2 belt driven) and in capacities from 150 to 2,500 cubic feet per minute.

GOOD HUNTING

The finest hunting grounds in Canada—for big game and small game, are reached by the Canadian Pacific Railway. Amongst the best must be reckoned the country adjacent to the recently opened Toronto-Sudbury line—alive with moose, deer, bear and every variety of game. This will be the first Fall this country has been accessible by rail. Go up while the hunting is at its best.

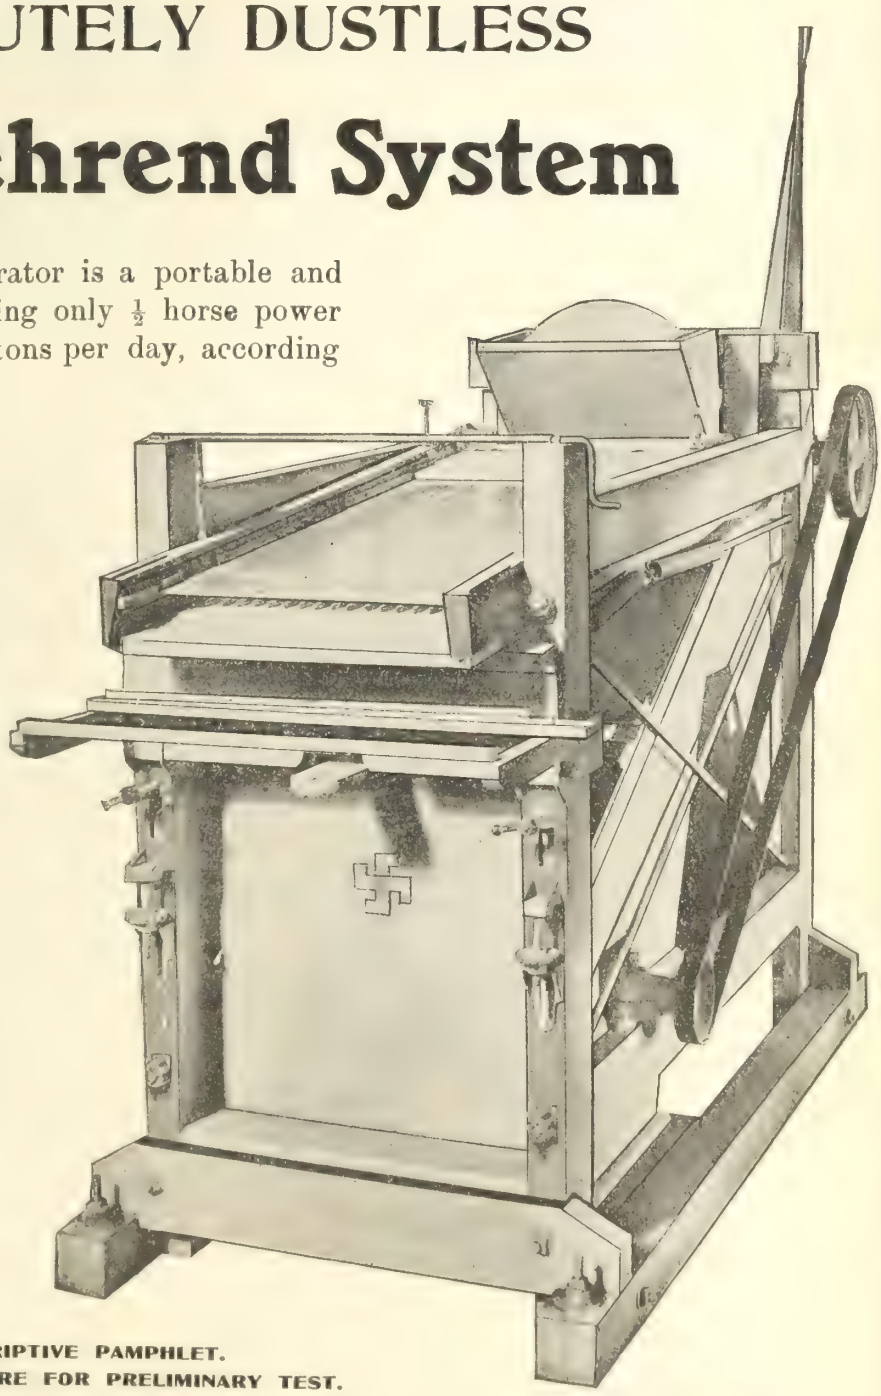
Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System



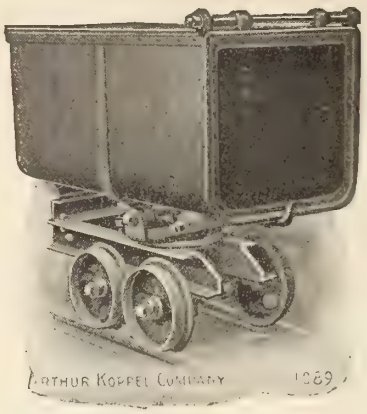
The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.



WRITE US FOR DESCRIPTIVE PAMPHLET.
FORWARD SAMPLE OF YOUR ORE FOR PRELIMINARY TEST.

THE CANADIAN MINING JOURNAL

VOL. XXIX. TORONTO and MONTREAL, September 1, 1908 No. 17

The Canadian Mining Journal

With which is incorporated the
"CANADIAN MINING REVIEW"
Devoted to Mining, Metallurgy and Allied Industries in Canada
Published fortnightly by the

MINES PUBLISHING CO., LIMITED

Head Office - - Confederation Life Building, Toronto.
Branch Offices Montreal, Halifax, Victoria, and London, Eng.

Editor:
J. C. MURRAY, B.A., B.Sc.

Business Manager:
J. J. HARPELL, B.A.

SUBSCRIPTIONS—Payable in advance, $2.00 a year of 24 numbers, including postage in Canada. In all other countries, including postage, $3.00 a year.

Advertising copy should reach the Toronto Office by the 8th, for the issues of the 15th of each month, and by the 23rd for the issues of the first of the following month. If proof is required, the copy should be sent so that the accepted proof will reach the Toronto Office by the above dates.

CIRCULATION.

During the year ending with March 1st, 1908, 91,750 copies of "The Canadian Mining Journal" were printed and distributed, an average of 3,822 per issue.

"Entered as second-class matter April 23rd, 1908, at the post-office at Buffalo, N.Y., under the Act of Congress of March 3, 1879."

SPECIAL CONTRIBUTORS.

Geology: Dr. Frank D. Adams, McGill University; Dr. A. E. Barlow, late of Geological Survey of Canada; Professor Willett G. Miller, Provincial Geologist of Ontario; Dr. J. E. Woodman, Dalhousie University, Halifax, N.S.

Chemistry: Dr. W. L. Goodwin, Director School of Mining, Kingston, Ontario; Milton Hersey, M.Sc., Official Analyst Province of Quebec.

Mineralogy: Professor W. Nicol, School of Mining, Kingston, Ontario.

Mining: S. S. Fowler, M.E., Nelson, B.C.; Frederick Keffer, M.E., Anaconda, B.C.; A. B. Willmott, M.E., Sault Ste. Marie, Ont.; J. C. Gwillim, M.E., School of Mining, Kingston, Ont.; J. Obalski, Inspector of Mines, Quebec; J. Bonsal Porter, M.E., McGill University; H. Mortimer-Lamb, Sec. Can. Min. Inst.; John E. Hardman, M.E., Montreal; Fritz Cirkel, M.E., Montreal; George W. Stuart, M.E., Truro, N.S.

Metallurgy: Stafford F. Kirkpatrick, School of Mining, Kingston, Ontario; A. P. Scott, Dominion Iron & Steel Company, Cape Breton.

THE CANADIAN ANNUAL REVIEW OF PUBLIC AFFAIRS, 1907.

Mr. Hopkins' labors are of immediate use and of future value. The Annual Review gives a comprehensive account of the political, financial and industrial progress of Canada during the past year.

Part of Section IV. is devoted to mining. The operations of boomsters at Larder Lake and the aid vouchsafed these malign operators by the Toronto newspapers, are the text of a considerable part of the chapter.

Mr. Hopkins states, in referring to the case of Law & Co., that proceedings were initiated by the Provincial Secretary's Department. This is an error. The Canadian Mining Journal succeeded, after weeks of futile effort, during which several Toronto newspapers refused to take up the question in any manner, in instituting proceedings against Law for breach of the Ontario Companies Act. The whole work of investigation fell upon the Journal. Later, when at the instance of the Journal more serious charges were laid, the Department acted promptly.

Any opinion, separated from its context, may take on a meaning that it was not intended to have. The Annual Review quotes us as declaring that Larder Lake would never be anything but a low-grade camp at best. This opinion was accompanied by a statement that so little was known of the district that no final opinion could be formed. While we have but slight reason to modify this dictum, the known occurrence of bonanza ore on one or two claims lends a more cheerful aspect to the yet undeveloped region.

We note with pleasure the amount of space devoted by the editor of the Annual Review to the industry whose welfare is our especial object. Incidental errors are bound to occur; but in the main Mr. Hopkins summary is broad and accurate.

Mr. Hopkins has some words of praise for our banking system. As the mining industry is, to a marked extent, dependent upon the attitude and policy of the banks, it is not amiss to notice a few facts not mentioned in the Annual Review. The public generally has little conception of the true conditions that underlie "tight money." It is a condition that could not prevail were our banks true to the interests of the country. Moreover, the enormous current of money that finds its way out of Canada and into New York in the shape of call loans is a constant handicap to the progress of our industries.

A startling feature of our banking system, one that makes absurd all loud boastings as to inherent stability and soundness, is the little known fact that our paper currency has no gold reserve behind it. It is true that the Government paper notes of low denomi-

nation are supported by a reserve of gold and Imperial bonds. But our bank notes are absolutely devoid of gold backing.

Thus, while Mr. Hopkins is perhaps just in his praise of the prevision of certain bankers who warned the public early in 1907 to restrict their operations, he could truthfully add that this warning would not have been needed did we not possess one of the most lamentably weak, illogical and flimsy systems of banking that the world has ever seen.

The public usually believes what it is told to believe, especially if its information comes from dignified sources. How it has been led into accepting the totally inaccurate impressions that are current regarding Canadian banking methods is hard to imagine. If our insurance companies needed investigation, and even Mr. Hopkins does not affirm to the contrary, then the banking corporations also needed probing. Not until the evils that are sapping the foundations of our national health have been rectified will our industries progress as they should. With a sound banking system, a currency that is not merely paper, and legislative restraint on the exportation of our earnings, panics and depressions would not occur with such mathematical regularity.

It is apparently impossible to induce our newspapers to take up questions of this sort. The overwhelming influence of corporations converts most of our writers and publicists into phonographs and lickspittles. The man who dares to speak his mind is systematically blackened in reputation and can get no hearing. Therefore our principal need, as a nation, is a plentiful supply of fearless and informed writers who will neither sell their souls for that which is not, nor bow the knee to Baal.

All of which has little to do with Mr. Hopkins' excellent, painstaking and inoffensive volume. Mr. Hopkins may be neither a prophet nor the son of a prophet. It is wildly improbable that upon so industrious and appreciative a person as he, will fall the disagreeable burden of writing of things as they are—not as we are told they are. Rather is Mr. Hopkins an ardent believer in constituted authority, in the divine right of banks and the eternal usefulness of buncombe.

THE BOSTON-RICHARDSON.

Readers of the Canadian Mining Journal are familiar with the operations of the Boston-Richardson gold mine.

For some years this mine has been a steady producer. The ore worked is low grade, the gold content averaging not more than $3.00 per ton. The equipment consists principally of a sixty-stamp mill (we are informed that forty additional stamps are being installed), six Wilfley tables and a bromo-cyanide plant.

During the year ended September 30, 1907, 43,456 tons of ore were crushed, yielding 6,504 ounces of gold, an average of about $2.85 per ton. The total cost of operation, per ton of ore milled, amounted to about $1.90. Thus a net profit of $41,283 should be expected. However, during the past year large sums have been expended in enlargement of plant. Moreover, during July of this summer, the ore suddenly dropped in value. The drop was not sufficiently pronounced to have affected operations vitally at a time when the company was not embarrassed. For instance, if the mine had been working normally with its enlarged plant in full operation for a period of twelve months, working profits could have been counted upon to straighten matters out. For, although the margin of profit is small, it has heretofore been constant, and the company was acting in accordance with sound business principles in adding to their plant.

But a combination of misfortunes, including tight money, has crippled the operators of the Boston-Richardson and, unless immediate steps are taken, gold mining in Nova Scotia will have received a fatal blow.

The avowed policy of the Government of Nova Scotia has been to encourage gold mining by all legitimate means. On certain deep mining operations actual financial aid has been offered. But very few operators, if any, have availed themselves intelligently of the Government's offer.

In the case of the Boston-Richardson, we have an example that is worth dwelling upon. The operators have put up an arduous and plucky fight. The sturdy faith of the management in themselves and in the mine has been justified by several years of successful operation. They have met difficulties and discouragements with fortitude and equanimity. Their mine has been a bright spot in the recent history of Nova Scotia gold mining. If that bright spot be now eclipsed the consequences will be disastrous in the extreme.

In view of all this we venture to submit that this is an opportune moment for the Government of Nova Scotia to step in and proffer its assistance. Such a course is fully warranted by precedent. The action of the Ontario Government in helping the Sault Ste. Marie industries is a case in point; and there are many other analogous incidents.

Just what form such assistance should take we can not presume to say. There are several possible channels. A temporary loan might meet the requirements; Australian governments have sanctioned this expedient. Or, as an alternative, the Government might become a permanent partner in the enterprise. If justification is required for this course, the attitude of the Ontario Government may be cited.

But whatever may be decided upon, it is absolutely certain that allowing the Boston-Richardson to be set down as a failure will prove the most costly and unprofitable step of all.

We have no doubt that the enlightened and progressive Government of Nova Scotia will investigate the situation thoroughly.

GAS PRODUCERS—THEIR PRESENT LIMITATIONS.

For at least thirty years gas engines have been in use. Only within the last decade, however, have large engines been put into service. The general adoption of the gas engine depended upon the production of cheap gas and the modern gas producer has provided the key to this problem.

The first producers were of the suction type, in which the suction stroke of the engine develops its charge of gas in the producer. No tarry or bituminous fuels could be used in these. Hence the only fuels available were anthracite coal, coke and charcoal. Although these limitations are being overcome, they have been and are characteristic of suction gas producers.

The pressure gas producers, in which the gas is generated under pressure and stored in a holder before being used, thus affording an opportunity for removing the impurities, is capable of utilizing bituminous coal and lignite. Peat also can be safely used, although it has not until recently proved a commercially successful fuel.

The invention of the pressure gas producer was followed by the appearance of a third type—the down-draft producer. The latter consumes completely the hydrocarbons resulting from the destructive distillation of coal.

Although in all three types of producers anthracite coal has been most commonly used, yet the tendency of late has been towards the use of bituminous coals, lignite, and peats. Suction plants are confined to small units. The larger gas producers are of either the pressure or down-draft type.

Comparing results obtained at highly efficient plants, when 10.3 per cent. of the energy stored in coal is utilized at a steam plant, the results are considered highly satisfactory. Good gas producer practice calls for the utilization of 24 per cent.

Under equal conditions, tests to determine the relative efficiency of steam plants and gas-producer plants have resulted uniformly in favor of the latter. In addition to this it has been found that low-grade coals of little or no value under the boiler, will give good results in the gas producer. This is an important point perhaps the weightiest argument that can be adduced when many of the coals of the Dominion are to be dealt with.

Despite the various advantages of the gas producer all is not plain sailing. Several considerations militate against its more general adoption; and it may be worth while recounting a few of these.

There is no doubt that the best makes of gas producers are reliable and highly efficient. Unfortunately there are many poor and untrustworthy makes being sold and installed. The failure of these machines has created much prejudice. Moreover, equally bad results have been noted when inexperienced men have been placed in charge of thoroughly good installations. These are probably the chief causes of public prejudice against or indifference to the claims of the gas producer. But the limited range of fuels that can be used in certain types of producers, the high initial cost as compared with steam-power plants, the inability of most types of producer to use bituminous coals, and the imperfect or unsuitable design of many gas engines —all these factors contribute to delay a wider demand.

It may be safely concluded that both manufacturers and purchasers need more light. Manufacturers are far too prone to drop all responsibility after a plant has been sold. On the other hand, purchasers do not take the trouble to investigate for themselves.

FERNIE.

The first appeal of the sufferers in the Fernie fire has met with a hearty response. Money and supplies have been forthcoming from all parts of Canada. The catastrophe was unique. It was spectacular. It caught and held public attention for a longer time than is usually the case.

Generously as help has been given, the situation at Fernie is by no means relieved. Winter is approaching and unless much larger donations are received by the Relief Committee there will be lamentable suffering with the advent of cold weather.

There is no need of urging the neighboring towns of Southern British Columbia to do more. They have already given unsparingly and are continuing to give.

But upon the cities and towns of Eastern Canada there will rest a stigma if they do not voluntarily come to the assistance of the stricken townspeople of Fernie. Especially is it the duty of mining centres, such as Cobalt, Sudbury, Glace Bay and Thetford to contribute according to their means. In Glace Bay there is already a movement on foot to raise money for the Relief Fund. Let other mining towns follow her good example.

Quite apart from all considerations of sentiment, it is the duty of every citizen of Canada to see that Fernie gets a fair start in her brave attempt to rehabilitate herself.

THE SUMMER EXCURSION.

A few days after this number of the Canadian Mining Journal has been distributed the Canadian Mining Institute excursionists will reach Toronto. Before arriving here the members and their guests will have visited the Dominion coal collieries at Glace Bay, the Dominion Steel Company's large works at Sydney, the Nova Scotia Steel and Coal Company's plant, the Pictou coal fields, and the iron ore deposits and workings of the Drummond interests at Torbrook, Nova Scotia. On their way through Quebec they will have surveyed the famous asbestos districts of that province. Therefore, the foreign delegates will have received a fair, though quite incomplete, impression of the directions in which our eastern mining industries are to expand.

After being entertained at Niagara and Toronto for two days the excursionists will proceed to Cobalt, Sudbury, Moose Mountain, in Western Ontario, through Alberta and, finally, through Southern British Columbia.

Extensive as is this itinerary, and numerous as are the mining districts to be visited, there are as many, or more, equally interesting and not less important, that the excursion cannot touch. Among the list of unvisited sections are the gold, antimony, manganese and gypsum districts of Nova Scotia; the manganese, iron, and gypsum bearing areas of New Brunswick; the vast hinterland of Northern Quebec, whose mineral possibilities we yet can only guess at; the varied deposits of Frontenac, Hasintgs and Renfrew counties in Eastern Ontario; the oil and gas fields to our south, and the gold, mica, antimony, coal and copper of Northern British Columbia; not to mention the reviving gold industry of the Yukon.

Therefore, it will be well for our visitors to bear in mind the fact that they are touching but the fringe of Canada's mineral belts, and that her mineral wealth is most inadequately known even by Canadians themselves.

SAFETY LAMPS AND COAL DUST.

Mr. James Ashworth, in his evidence before the British Royal Commission on Safety in Mines, developed the view that each floating particle of coal dust is sustained by a quantity of occluded hydrocarbon gases, and is capable of passing completely through both sides of the gauze of ordinary safety lamps. This is taken to be the cause of many hitherto unexplained explosions in coal mines.

The Colliery Guardian, for August 1, publishes as a supplement a digest of the Reports of H. M. Inspectors of Coal Mines. This is the second annual supplement of the sort. A few notes abstracted from the digest appear on another page of the Canadian Mining Journal.

The July Bulletin of the Canadian Mining Institute reflects credit upon the secretary, Mr. H. Mortimer Lamb. That he has been energetic and importunate in pressing his requests for technical articles is evident from the number of papers included. The Bulletin is an improvement upon its predecessors in the matter of editing. This is the more creditable when we remember that arrangements for the present summer excursion must have taken up much of the secretary's time.

THE GREAT WAIHI MINE.

Written for The Canadian Mining Journal by J. M. Bell, Director of the Geological Survey of New Zealand, and Colin Fraser, Mining Geologist.

(*Continued from last issue.*)

Origin of the Veins.

The formation of the Waihi veins, which was contemporaneous with the propylisation of the dacites enclosing them, was evidently the result of hydrothermal activity. Since the rhyolites super-imposed on the dacites contain in this locality no quartz veins, it is presumed that the formation of the veins and the propylitisation of the dacites preceded the outpouring of the rhyolites. It is interesting in connection with the hydrothermal origin of the veins to note that notwithstanding the general percolation of cold water from the surface and good ventilation, the temperature of the mine waters is considerably above the mean average temperature at the surface. The latter is about 54° Fahrenheit, while temperatures of the mine waters as high as 85° Fahrenheit have been recorded.

Vein formation as the result of the circulation of heated mineralized waters appears to have been due to:

(1) The complete or partial metasomatic replacement of the country rock by the materials brought in solution in the ascending waters.

(2) The deposition in open spaces of vein material brought in solution by the ascending waters.

These two phases of vein formation appear to have taken place along a rather complicated system of zones of multiple fracture or faulting. Metasomatic replacement of the country rock may be considered to have proceeded gradually from the more or less parallel fissure of each individual zone. The metasomatic replacement, rather than the filling of pre-existing open spaces, seems to have been the more important.

As mentioned before, the banded sulphide ores which were deposited in small, irregular fissures, carry high values in gold and silver—higher values than the replacement sulphide ores. Since these rich veins are in the main later than the replacement ore, it is possible that the richness of their values may be the result of a concentration of the values formerly in the replacement ore, by later ascending solutions. On this point, however, the writers of the present paper do not feel prepared to commit themselves until more detailed macroscopic and microscopic work than that already done has been completed. Apparently the propylitized dacite which forms the wall rocks in all the veins has not exercised any particular influence on the actual position in the veins of the pay ore deposited, since the values, though occurring more frequently on the foot-walls in the higher levels, are found elsewhere on both hanging and foot walls and throughout the veins.

It is significant that the deposit of richest ore in the Waihi Mine occurs in the Edward, near its junction with the Empire and the Welcome, and not far from the horizon where the latter and its two branches, the Regina and the Magazine, join the Martha. This bonanza may indicate an enrichment by mingling of ascending solutions.

The somewhat distinct separation of the non-payable vein material from the sulphide ore would seem to indicate that the deposition of the two was not contemporaneous. However, there is no very direct evidence on this point.

The presence of silicious sinters at the surface of the Martha lode, the absence of a gossanous outcrop, and the fact that many of the veins of the Martha system do not reach the surface, all show how limited has been the removal of auriferous material by erosion.

Mining and Treatment of the Ore.

Method of Mining.—The topographical features of the area enclosing the great gold-silver veins of the Waihi Mine admitted of only a limited amount of the ore being mined from open cuts or adits, and the supply from these workings is now almost exhausted. Principal access to the extensive underground workings is afforded by five vertical shafts, located as shown on the plan. Sinking is still proceeding in certain of these shafts, the deepest (No. 5) now extending to 1,020 feet below the surface. Drainage is effected from the most centrally situated shaft (No. 5) by means of two powerful pumps of the Cornish type. The volume of water raised has heretofore shown a gradual increase with depth, and at the lowest (850 ft.) level, which intersected all the veins, amounted to 900 gallons per minute. The conditions, however, at the 1,000 ft. level now in course of excavation are suggestive of less water existing in the deeper ground.

The principal working levels, of which there are nine below the adit, are spaced at vertical intervals ranging from 60 ft. to 150 ft. apart. Both the cross-cuts and the drifts along the lodes in these levels are provided with single or double tramways.

Timbering in the mine is reduced to a minimum owing to the good standing qualities of the ground. Only along the drifts on the veins stoped, or to be stoped, are the sets of heavy squared timber (kauri or rimu—New Zealand conifers) in evidence.

The ore was in the past mined by the usual system of rising and overhand stoping, followed by the filling in of the stoped ground with soft weathered rock excavated in open cuts and sent down through special passes. Now, however, the "shrinkage" method of stoping, a modification of the Alaska Treadwell caving system, is employed wherever the vein walls are good and the ores require no sorting. The passes from the stopes to the levels below in this case are never more than 10 ft. apart, and are placed in zig zag arrangement along the floors of the stopes. When stoping is completed in a block the ore is drawn off as required, starting from the "end of ground," and filling material is run in to replace it. Any ore left as small cone-shaped heaps between the closely-spaced passes is finally drawn off by temporarily cutting away a slab or two in the roof of the level under these particular points.

The propylitized, much silicified, dacite of the Waihi Mine, is fairly hard, breaking frequently with an almost splintery fracture, and is characterized by singular uniformity throughout the mine. The country rock in the cross-cuts and along the vein, and the vein material itself, usually stands remarkably well. The good standing qualities of the vein material is well exemplified in the stope on the Edward lode, just above the 850 ft. level. Here a width of 75 ft. of ore is exposed overhead for a considerable distance on the course of the vein without support of any kind from below.

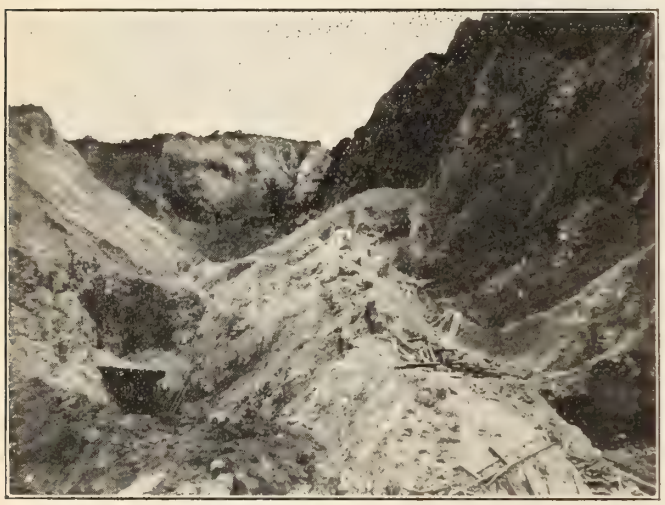
Air-driven rock drills, mostly of the Ingersoll type, are employed both in the cross-cuts and drifts and in the stopes.

The transit of the ore from the passes in the levels to the winding shafts is effected in large trucks. Until quite recently all these trucks of ore were raised in cages to the surface, and the ore was there dumped into large hoppers. The substitution of self-dumping three-ton skips for cages at No. 6 shaft has effected a marked advance in the lifting of the ore to the surface. On the 12th May, 1908, the record amount of 1,559 tons of ore was lifted from the mine, and 750 tons of filling-in material sent down.

MARTHA HILL AND RIDGE LOOKING WESTWARD.

Key—A—Waihi Grand Junction Co.'s No. 1 Shaft; B—Waihi Co.'s No. 2 Shaft; C—Waihi Co.'s No. 1 Shaft: D—Open Cut on Martha Hill E—Waihi Co.'s No. 6 Shaft.

Railway lines equipped with light locomotives and side-dumping steel cars connect the surface ore bins at the various winding shifts with the metallurgical plants to be later described.



Steam is the motive power employed at the mine for all purposes, the fuel being lignite of fair quality railed from the collieries of the Waikato, some 70 miles distant.

The Metallurgical Works.—The metallurgical works comprise three separate mills, containing in all 330 stamps, rock-breakers, tube-mills, concentrating machinery, cyanide plants, melting, assaying, and refining plants, and all accessories. The three separate mills are known as the Martha (90 stamps), the Union (40 stamps), both situated at short distances from the mine, and the Waikino (200 stamps), situated at the village of Waikino, some five miles from Waihi.

The Martha, which may be taken as a type of the three mills mentioned, will be briefly described.

The ore railed from the mine is first dumped into an elevated hopper in the back of the mill. From this hopper the ore is screened on a "grizzly" and the coarse material passed through two rock-breakers of the Gates type—a large one and a small one—working in series.

The crushed ore from the breakers and the fines from the grizzlies fall on to a belt conveyor which delivers it into a series of bins located behind the stamps. The stamps are fed by Challenge ore-feeders with the broken ore from the bins mentioned. These stamps, each weighing 1,000 lbs., fall with a six-inch drop 103 times per minute, and have a duty of 3,794 tons per day. The ore is wet-crushed, the discharge screens of the stamper-boxes having a 10, 20 or 25 mesh, according to the tube-mill capacity available. The pulverized ore from the

OPEN CUT ON MARTHA LODE.

The clean-cut face is the footwall of the lode.

stamps is conveyed by launders to classifiers of the Spitzhasten type, the coarse material from these being subjected to further grinding in tube-mills.*

The product of these wet-crushing tube-mills is itself subjected to classification, the fines joining those directly obtained from the stamps, while the coarser sands are elevated back to the mills for further comminution and subsequent classification.

The whole of the pulverized ore from the stamps and the tube-mills is conveyed in launders to the amalgamating room. Here it passes over silvered muntz-metal tables, where recovery of that portion of the gold-silver which exists in a free state is effected by amalgamation with mercury.

Classification of the ore is the next process, and is effected in "Spitzkastens," the slimes, to which finely ground lime is added, settling in large steel vats, and the fairly clear overflow water returning for use in the stamp mortars.

The sands only are conducted in launders to the vanners, which are mainly of the Union, but partly of the Wilfley type.* The concentrates, which amount to 1.56% of the ore and carry 18.14% of its total value** are, together with those from the Union 40-stamp mill, railed to Waikino for treatment. Reference will be made later to the process employed in dealing with the concentrates at Waikino.

The sands deprived of their concentrates are carried along in launders and delivered through Butter's distributors to the cyaniding vats. Here they are subjected to the usual direct treatment, which for each charge takes about seven days. The vats are mainly about 22 ft. in diameter, and 4 ft. 6 in. in depth.

In the cyaniding of the slimes from the Spitzkastens the agitation method, coupled with the employment of vacuum filter frames or baskets, has superseded all other methods. In this process the liquid slimes are run into vats, where they are kept from settling by agitation with compressed air. Into these vats the baskets, hung from a travelling overhead crane, are lowered. On the application of the vacuum, each basket takes up its load of slimes practically free from water, and on being raised, conveys it to an adjoining compartment. Here the pulped slime is blown off, thoroughly disintegrated and mixed with cyanide solution, after which it passes into vats, and is there kept in constant agitation by compressed air. When the leaching of the gold-silver contents of the slimed ore has been completed, the leached slimes and the solution are transferred to vats, where the slime is extracted as pulp by baskets, and, after being washed free from solution, is blown off the baskets and sluiced into the tail race.

The method of the treatment of the concentrates at the Waikino Mill consists in further comminution of the material in tube-mills until it is reduced to an exceedingly fine slime. The slimed concentrates are then cyanided by a compressed air agitation method, a stronger solution of potassium cyanide being employed here than in dealing with the ordinary sands and slimes.

The gold and silver is in all cases recovered from the cyanide solutions by the usual method of precipitation on zinc in extractor boxes; partially spent sulphuric acid from the refining plant, to be later described, is employed instead of the usual roasting for the elimination of the zinc. The precipitated bullion, which on being melted is cast into thin, flat plates, is passed on to the refining works. According to assay, 89.0% of the total gold values of the Waihi ores, and some 70.3% of the total silver values, were extracted in 1907.

THE EDWARD VEIN—SEE PLAN—WAIHI MINE.

Vein is 30 feet wide here. It attains a maximum width of [illegible] feet and [illegible] throughout [illegible]

Power for both the Martha and the Union Mill is derived partly from water and partly from steam. The Ohinemuri River and one of its tributaries have separately been harnessed to supply power to the large Waikino Mill. This hydraulic power, however, is insufficient

*A special feature in the mechanism of the Waihi Company's tube mills are the "Honeycomb" liners—slabs of silicious sinter or hard chalcedonic quartz obtained in the vicinity of the mine being cemented into honeycombed steel frames.

*Twenty-three of these in the Martha Mill are Union and one Wilfley.

**1907 Annual Report of the Waihi Gold and Silver Mining Company.

to meet the ever-increasing demands, and steam is employed as at the other two mills. To the Waikino steam plant has recently been added a 2,000 horsepower producer gas plant, Waikato lignite being used in the manufacture of the gas. This gas power plant, which is in three units—one of 1,000 h.p. and two or 500 h.p.—is proving both economical and efficient.

In conjunction with the Waikino Mill are both a foundry and engineering works, and a saw-mill. The former is of considerable capacity, and turns out a great part of the new mining and milling machinery, and effects all the necessary repairs and renewals. Fine milling timber, both kauri and rimu, is derived from sev-

eral forest reserves which are in possession of the Company.

The Refining Works.—A plant for the refining of the whole of the Waihi Company's gold-silver bullion by the sulphuric acid process has recently been installed at the Martha Mill. The bullion in the form of thin plates is heated with concentrated sulphuric acid in three large iron crucibles, each holding 7,000 ozs. The mother liquid containing the silver, after being siphoned off into a settler, is passed on to a cistern, where it is diluted with steam and cooled. Here the silver sulphate crystallizes out, forming a thick incrustation on the sides and bottom of the cistern. This silver sulphate is reduced to the metal by the passage through it of a solution of ferrous sulphate, the silver precipitate being washed, dried, and melted into bars. The ferric sulphate formed in the re-action between the silver sulphate and the ferrous sulphate is again reduced to ferrous sulphate by the addition of metallic iron. The gold remaining in the three crucibles is brought together in the central one, and there receives a final heating with strong sulphuric acid to further purify it. The gold, now in a granular state, is washed, dried and melted into ingots, which range from .990 to .993 fine. A little copper is added if necessary to increase the malleability of the gold. Since the output per month is about 15,000 ozs. of gold, and from 120,000 to 130,000 ozs. of silver, the total weight of bullion handled in this period is between four and five tons.

As a by-product in the gold-silver refining process, a certain amount of silenium which occurs in the bullion is recovered. The last shipment of this element exported sold for about £80.

Cost of Mining, Treatment, Etc.

The total expenditure (£357,674) of the Waihi Company for the year 1907, when 356,974 short tons of ore were treated, gives the approximate cost per ton as under:—

	£	s.	d.
Mining—			
Stoping and general mining expenses....		7	2.36
Development work		1	4.52
Transport of ore to mills			3.67
Metallurgical treatment of the ore, from the initial crushing to the production of the refined gold and silver bars		7	11.39
Freight, insurance, and expenses of realising bullion			4.93
Repairs and renewals to plant, building machinery, and water-races			3.68
Export duty on gold, and rent paid to the N. Z. Government		1	0.08
Salaries, office rent, and miscellaneous expenses in New Zealand		1	0.95
Directors' fees, salaries and expenses in London			4.88
Total	£1	0	0.46

amount paid in dividends, bonuses, etc., up to the 31st December amounted to £2,871,328, or 45.64% of the total value of the gold-silver produced. The company's reserve amount at date mentioned stood at £140,000. In 1907 the total distribution to shareholders was 80% on the capital, or 8½% on present share values. Ore in sight at the end of the year 1907 was estimated at 1,299,979 tons, or about four years' supply at the present rate of milling. This calculated reserve exceeded that of the previous year by 270,321 tons. Its average value may be assessed at £2-14-0 per ton.

Certain of the figures just cited indicate that the prosperity of the Waihi Company is well assured for several years to come.

In speculating upon the future of the Waihi Mine, the following points are of interest:—

(1) All of the principal veins of the Waihi Mine exhibit a gradually increasing width without diminution in the tenor of the pay ore, when traced downward to the present lowermost level (850 ft.)

WAIHI GOLD MINING COMPANY'S VICTORIA MILL, WAIKINO.

Comprises 330 stamps, tube mills, concentration and cyanide plants; also foundry and engineering works and sawmill. The Government Railway passes in front of the mill.

Statistics and Future Prospects.

The total amount and value of the ores produced by the Waihi Gold Mining Company, Limited, from the date of its formation to the 31st December, 1907, is as under:—

	Tons (2,000 lbs.)	Yield.	Total.
To Dec., 1891 ...	(not recorded)	50,086	50,086
1892-1899 (incl.).	394,374	1,152,138	
For year 1900....	125,453	317,902	
For year 1901....	178,444	461,205	
For year 1902....	201,023	521,574	
For year 1903....	259,082	658,393	
For year 1904....	291,176	683,888	
For year 1905....	298,531	728,521	
For year 1906....	328,866	837,927	
For year 1907....	356,974	878,486	
	2,433,923 tons valued at		£6,240,034
Total value of output.....			£6,290,120

The Waihi Gold Mining Company, Limited, is capitalized at £500,000, in 500,000 shares of £1 each, which have a present market value of about £4,750,000. The

(2) In the neighbouring Grand Junction Mine boring has proved that high grade sulphide ore exists at a depth of 150 feet below the Waihi Company's lowest level (850 ft.)

(3) On the Talisman Gold Mining Company's property, some 8½ miles eastward from Waihi, rich sulphide ore in andesites is being mined at a depth of 2,000 feet below the outcrop of the Talisman vein. In the Waihi Mine the greatest vertical range yet exploited on the outcropping Martha vein is 1,055 feet.

(4) Since, as already mentioned in this paper, many of the veins in the Waihi Mine do not reach the surface, while some of the outcrop quartz has the character of sinter deposits, it may be inferred that there have been but little erosion of the surface and little removal of auriferous vein-stone since the formation of the lodes. Consequently there can have been only slight secondary enrichment by descending surface water. Thus it may be concluded that the present values of the lodes are practically original, and may be expected to continue to considerable depths.

These facts, taken in conjunction with the increasing output, augur favorably for the future of the great Waihi Mine in depth.

Annual Report of the Coal Mines Branch, Department of Public Works, Alberta, for the Year 1907.

The report of the Coal Mines Branch states that, with the exception of a short period of idleness following a general strike, the year 1907 was one of steady activity and substantial progress. The total output of coal was 32.47 per cent. greater than in 1906.

Year.	Output of coal in tons.	Per cent. increase over previous year.
1905	811,228	.....
1906	1,385,000	70.73
1907	1,834,745	32.47

The coal output for 1906 and 1907 is thus classified:

	1906. Tons.	1907. Tons.
Lignite	602,780	639,335
Bituminous	546,623	939,295
Anthracite	235,597	256,115
Coal used in coke production	103,936	112,887
Coke produced	69,844	73,782
Briquettes produced	.....	49,585

It will be noticed that for 1907, by far, the largest increase is assigned to bituminous coal. As the quantity of coal converted into coke is not materially larger than that recorded in 1906, it is evident that domestic household and industrial (other than metallurgical) markets absorbed the balance.

A summary of statistics for the two last years offers a fair means of estimating the growth of the industry:

	1906.	1907.
Number of new mines opened	16	35
Number of old mines reopened	..	2
Number of mines abandoned	2	6
Number of tons of coal produced	1,385,000	1,834,745
Number of tons of coke produced	69,844	73,782
Number of tons of briquettes produced	.....	49,585
Average number of persons employed inside the mines	2,000	2,700
Average number of persons employed outside the mines	800	900
Number of fatal accidents inside the mines	9	17
Number of fatal accidents outside the mines	1	2
Number of non-fatal accidents inside the mines	31	75
Number of non-fatal accidents outside the mines	..	11

While in 1906 there were 61 coal mines known to be in operation in 1907 there were 98 in all, of which 15 produced no coal during the year.

Coal is being mined in the south at many points along the Crow's Nest branch of the C. P. R., from Medicine Hat near the eastern boundary to Coleman near the western boundary. On the main C. P. R. line extension coal deposits are being worked at Canmore and Bankhead. In the Edmonton district numerous mines are in operation and at many outlying points remote from railways small mines, worked during the winter, supply local requirements.

put of about 1,500 tons per day, drawn from three veins. The briquetting plant installed by the Zwoyer Fuel Company, has been doubled in capacity and now produces 400 tons of briquettes per day. The anthracite breaker plant has been duplicated and other improvements made.

The H. W. McNeill Company, Limited, Canmore, has carried out large improvements. The main roads have been enlarged to allow the introduction of compressed air locomotives.

The International Coal and Coke Company, Limited, Coleman, has a daily output of 1,570 tons, which is soon to be increased. Two additional locomotives have been added to the haulage plant. Incandescent lighting has been introduced in the main gangway on No. 2 and No. 4 seams.

The Hillcrest Coal and Coke Company, Limited, Hillcrest, has installed a new fan to ventilate the whole of their mine. The capacity is 30,000 cubic feet of air per minute.

At the property of the **Maple Leaf Coal Company, Bellevue,** a new coal chute has been installed capable of handling 500 tons of coal per day. This mine is rated among the large future producers.

The reorganized **Galbraith Coal Company, Lundbreck,** has erected a tipple of 1,000 tons daily capacity.

Many other companies report progress.

Accidents.

All serious accidents in coal mines were carefully investigated during the year. Six lives were lost on account of a fire that started in surface buildings, but not a single fatal accident due to fall of roof or sides was reported. The number of accidents due to explosions of gas has been greatly reduced since the introduction of safety lamps into many of the mines. Accidents caused by mine cars were numerous, but in most cases not serious.

Many of the accidents reported are so slight as not to incapacitate the injured party for more than a few hours or a day at most.

Fatal accidents numbered 17 below ground, and two above. Serious accidents numbered 17 below ground and one above ground. Six of the serious accidents were due to falls of roof and sides, five to mine cars and three to explosions.

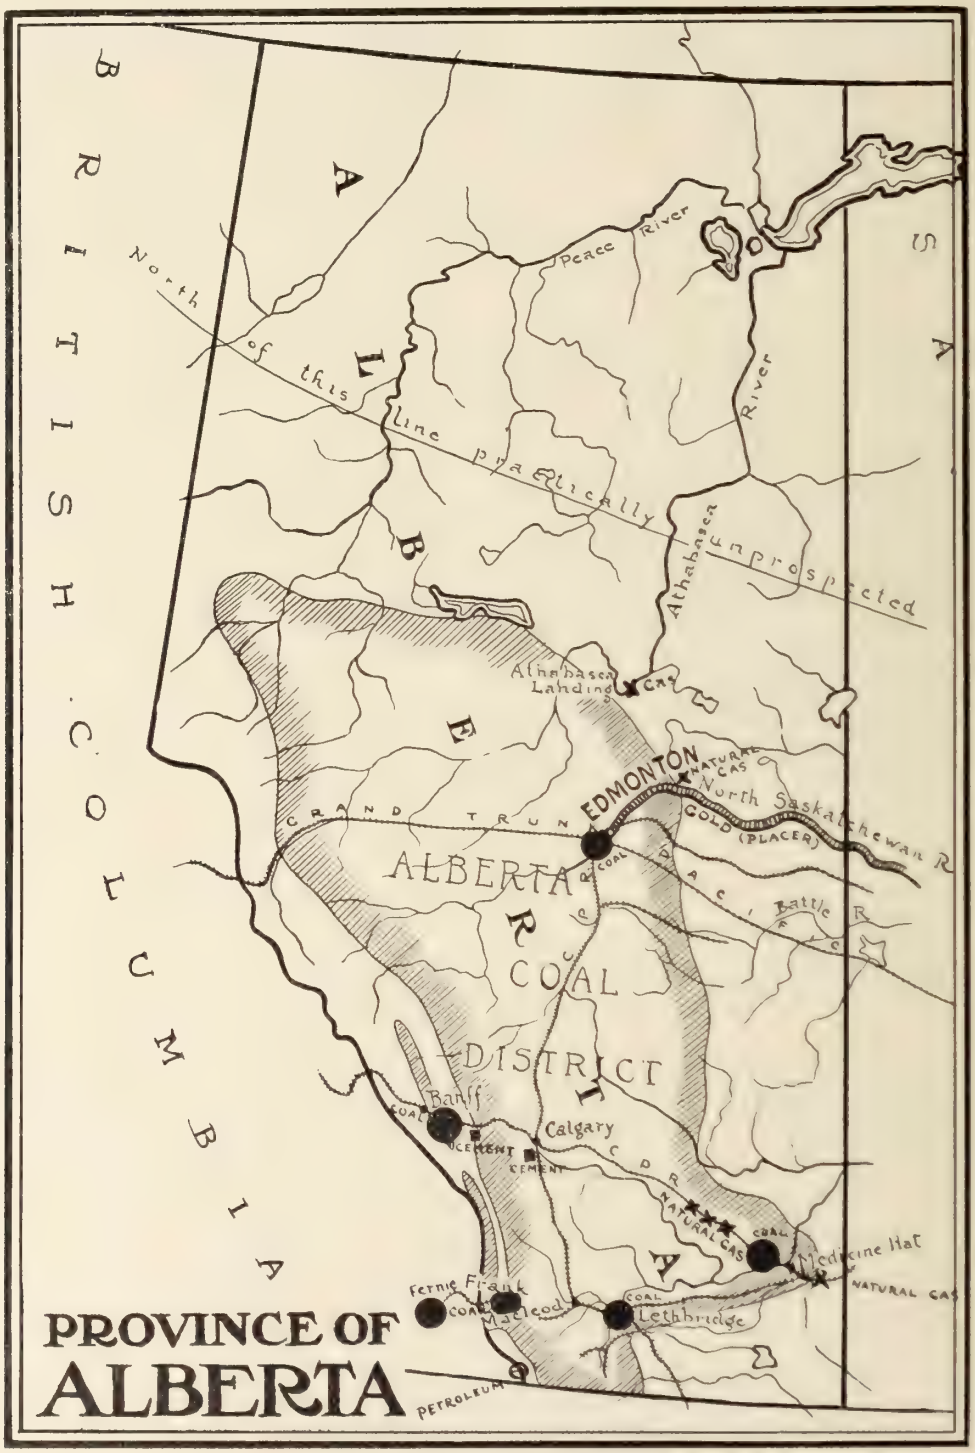
Taken in its entirety the list is by no means a large one, although the rate of fatalities underground per thousand men employed is excessively large, being 6.30 as against 4.5 for the preceding year. These high rates are of course due to the large number of mines opened, the crudeness of much of the mining and the extensiveness of the territory to be covered by the inspector.

Inspection.

Mr. Norman Fraser, Provincial Inspector of Mines, reports that he and his assistant made a continuous round of inspection of all the large mines and endeavored to visit the small outlying mines at suitable periods.

The use of locked safety lamps in mines where there is any danger of explosion from gas or dust has been enforced throughout the province. The introduction of

safety lamps has been opposed by some of the mines, but events have justified the measure.



The inspector alludes to the absence of any provisions in the Coal Mines Act bearing on the regulation of the use of explosives in dry and dusty mines. The keeping of necessary plans, records, registers and report books, is to be enforced.

Four prosecutions for breaches of the Coal Mines Act were undertaken by the department and in each case a conviction was obtained. These are the first prosecutions undertaken in the Province under the Coal Mines Act.

COAL BRIQUETTING.

Development of the Industry in 1907.

The coal briquetting industry should make rapid progress in this country during the next few years, according to E. W. Parker, of the United States Geological Survey. Although the production in the United States in 1907—63,153 short tons, having a value at the plants of $244,942—seems insignificant when compared with the output of briquetting plants in Germany in 1906—about 16,000,000 short tons—it is of great importance as indicating that a beginning has been made

and that consumers are being gradually educated in the advantages of briquets for efficiency, ease of handling and cleanliness.

There were ten plants in operation in 1907, although one of these, at Pittsburg Landing, Cal., was burned in July and up to the close of the year had not been rebuilt. The location of the plants and the character of the fuel and binder used in the operation are reported by Mr. Parker in a paper just published by the Survey as an advance chapter from "Mineral Resources of the United States, Calendar Year 1907." In the introductory paragraphs to this report Mr. Parker says:

"There can be little doubt that the interest aroused through calling attention to the waste in the past of the country's natural resources, represented by the non-use of slack and culm produced in our coal mining operations, and the aggressive policy of President Roosevelt in seeking to throw light upon it and to correct the abuses into which we have largely unconsciously fallen, are, to a great extent, responsible for the present prospect of a development of coal briquetting as an important industry in the United States. It may not be long before the governments of the States, under whose jurisdiction the matter comes, will enact legislation against the accumulation of slack and culm heaps or their useless destruction by burning and prohibit this waste, as they have in some cases interdicted the waste of natural gas.

"Legislation which would prohibit 'shooting from the solid' at mines, when slack coal is not a marketable product, and which would provide penalties for excessive use of powder would have, as one result, a larger percentage of lump coal, and thus, in part at least, enable operators to assume the additional expense involved in the briquetting of such slack coal as is unavoidably produced."

ALBERTA GOVERNMENT EXAMINATION FOR MINE MANAGERS, ETC.

Examinations.

Two examinations for fire bosses and one for mine managers and pit bosses have been held at each of the centres in the province. A large number of candidates presented themselves for examination. In the fire boss and pit boss classes most of the candidates came up to standard but in the managers class the majority of the candidates did not come up to the required standard.

The following are the questions set at the examinations in Banff, November 28th and 29th; Frank, December 2nd and 3rd; and Edmonton, December 5th and 6th, 1907.

Fire Boss Examination.

Paper No. 1. Time Allowed, Two Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Coal Mines Act.

1. What is required by the General Rules re fencing of places not in use in the mine? (10)
2. What is required by the General Rules re fencing of shafts? (10)
3. What does the Act require in the way of manholes on planes worked by machinery? (10)
4. What does the Act require in the way of manholes for travelling roads when the travelling roads are worked by horses or other animals? (10)
5. What does General Rule 2 state regarding ventilation and the daily inspection of mines by a competent person? (20)
6. What does General Rule 3 state regarding the daily inspection of mines by a competent person? (15)
7. Give a full description of the daily duties of a fire boss and write out an imaginary report on the conditions prevailng in a mine. (25)

Fire Boss Examination.

Paper No. 2. Time Allowed, Two Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Ventilation.

1. What is meant by ventilation and why is ventilation necessary in a mine? (10)
2. Describe fully all the gases found in mines. (20)
3. What is the essential difference between a safety lamp and an open light? (20)
4. Under what conditions may a safety lamp become dangerous? (15)
5. Describe with sketches all the different methods you know for conducting air to the face of rooms or rock tunnels when the face of these rooms or tunnels has got a considerable distance away from a cross-cut. (15)
6. How would you proceed to examine a mine for explosive gas, say fire-damp? (15)
7. Is it possible to have an explosion in a mine when a safety lamp test does not show any indication of fire-damp? Explain fully. (15)

Fire Boss Examination.

Paper No. 3. Time Allowed, Two Hours.

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

Practical Work.

1. Sketch and describe the mine in which you are at present employed. Show the direction of the ventilating currents and note the number of men employed and the average output for the day. (25)
2. In shot lighting a mine, what direction with relation to the direction of the air current would you travel in going your rounds? Give reasons. (20)

3. What precautions are necessary in handling dynamite and what precautions should a shotlighter take before firing any shot in a mine where safety lamps are used? (20)

4. Sketch and describe any two methods of timbering with which you are acquainted. (20)

5. Sketch and describe a good form of ventilation door to be used on a main haulage road. (15)

Fire Boss Examination.

Paper No. 4. Time Allowed, One Hour.

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

Arithmetic.

1. Divide 554.553 by 14.1 and multiply the result by the difference between three thousand and fifty-four and two thousand nine hundred and seventy-eight. (20)

2. What weight of coal will be produced from a level six feet high and eight feet wide and 1,000 feet long, supposing one ton in the solid occupies the space of 29 cubic feet? (20)

3. What is the area of an airway 6 feet 3 inches high by 10 feet 4 inches wide? (20)

4. If 100 cubic feet of air per minute is required for each man in a mine, how much air is required per minute in a mine working two shifts with 100 men on each shift? (20)

5. How many rails each 24 feet long will be required to lay double track in a main gangway 552 yards long? (20)

Pit Boss Examination.

Paper No. 1. Time Allowed, One and one-half Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Coal Mines Act.

1. What is the meaning of "mine" in the Coal Mines Act and to what mines does the Coal Mines Act apply? (15)

2. State all the provisions of the General Rules with regard to the inspection of mines. (20)

3. What are the provisions of the Act as to the use of safety lamps? (15)

4. What are the provisions of the Act governing the use of explosives below ground? (20)

5. What are the provisions of the Act regarding ropes and chains? (15)

6. State all the requirements of the Act regarding pit bosses and shotlighters. (15)

Pit Boss Examination.

Paper No. 2. Time Allowed, Two and one-half Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Ventilation.

1. Describe the various gases met with in mines, giving their chemical symbols and specific gravities. (20)

2. What methods would you adopt to obtain a large volume of air with the least possible mine resistance. (15)

3. What are the general requirements in regard to the use and construction of doors, overcasts and stoppings? (15)

4. Sketch and describe the water gauge and explain its use in ventilation. (15)

5. What dangers to life and property are to be guarded against when the ventilating current is produced by a furnace? (15)

6. In a mine the quantity of air passing is 25,000 cubic feet per minute, and the horse power of ventilation is 8. Find the water gauge. (20)

Pit Boss Examination.

Paper No. 3. Time Allowed, Three Hours.

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

Practical Work.

1. Sketch and describe how you would lay out and work a 5-foot seam of lignite with a soft roof under a cover of 200 feet. (20)

2. Sketch and describe how you would sink and secure a shaft through 6 feet of quicksand at a depth of 60 feet. (15)

3. Sketch and describe how you would timber a level running in a five foot seam of coal, pitching at an angle of 45 degrees to the horizontal. The level has to be 7 feet high from the low side rail and the coal is of a soft nature. (15)

4. What is your experience with explosives in mines, and what improvements do you think can be introduced regarding the class of explosives to be used in gaseous mines? (20)

5. Explain with sketches how you would extract pillars in a flat lignite seam with a clay roof and also in a pitching vein with a hard rock roof. (15)

6. If a fire breaks out suddenly in the downcast shaft of a mine what means would you adopt to secure the safety of the men in the mine underground? (15)

Pit Boss Examination.

Paper No. 4. Time Allowed, Three Hours.

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

Machinery.

1. What size and kind of rope would you put in a shaft for hoisting a load of 3 tons? Give weight of rope per foot and state size of pulley you would use for this rope. (20)

2. What is a syphon and what is the principle on which it works? (15)

3. Find the horse power of an engine having a 2 foot 6 inch stroke, diameter of cylinder 14 inches, effective steam pressure 60 pounds per square inch. (20)

4. Sketch and describe a fan suitable to ventilate a small mine. (15)

5. Describe with sketches some method of boring suitable for putting down test holes to a depth of 300 feet. (15)

6. What precautions would you take to ensure the safe and proper handling of boilers and what are the requirements of the Coal Mines Act regarding boilers? (15)

Pit Boss Examination.

Paper No. 5. Time Allowed, Three Hours.

The value attached to each question is given in brackets. Candidates must obtain 50 per cent. of the allotted marks to pass.

Surveying.

1. What is the cubic content of a mine car 5 feet long, 2 feet 2 inches wide and 20 inches deep. What weight of coal will this car hold when levelfull? (15)

2. What experience have you had in mine surveying? (15)

3. Plot the following survey.

(1) s. 20 degrees w. 220 feet.
(2) n. 40 degrees w. 140 feet.
(3) n. 20 degrees e. 220 feet.

Find the length and bearing of the closing line between points 1 and 3. (15)

4. What are the various reasons why plans should be kept of the workings of a mine? (20)

5. How do you put up points or plumbs to be used in keeping main roads straight in a mine? Describe fully how you line off these points afterwards, and take sights by them to the face of the road which has to be kept straight. (20)

6. What would be the cost of driving a tunnel 45 yards long, 8 feet wide and 7 feet 6 inches high, the price per cubic yard being $2.25? (15)

Mine Manager's Examination.

Paper No. 1. Time Allowed, One and one-half Hours.
The value attached to each question is given in brackets. Candidates must obtain 70 per cent. of the allotted marks to pass.

Coal Mines Act.

1. What is the interpretation of "mine" as laid down by the Coal Mines Act and to what mines does the Act apply? (15)

2. State fully the provisions and exceptions relating to the appointment of certificated managers. (15)

3. What are the provisions of the Act governing the use of explosives below ground? (20)

4. Name all the books, registers, reports, etc., required to be kept at the mine to comply with the Coal Mines Act. (20)

5. In what manner and to whom has notice of fatal and non-fatal accidents to be sent? What form is set out in the Coal Mines Act for the use of those making returns of facts relating to accidents or explosions? (15)

6. What does the Act say in connection with the appointment of inspectors by workmen? (15)

Mine Manager's Examination.

Paper No. 2. Time Allowed, Two and one-half Hours.
The value attached to each question is given in brackets. Candidates must obtain 70 per cent. of the allotted marks to pass.

Ventilation.

1. Name and describe the gases met with in coal mines and give the chemical symbol and specific gravity of each. (15)

2. Would there be any danger in a mine where the ventilating current contained 1 per cent. of CH_4 and also a considerable amount of fine coal dust? Give reasons for your answer. (10)

3. The old workings in a mine cover 20 acres, and the average height between roof and floor over this area is 2 feet. If this area is filled with CH_4 how much of that gas will be given off into the roadways of the mine if the barometer falls from 27.5 inches to 27 inches? (15)

4. The quantity of air passing in an airway 10 feet by 10 feet is 50,000 cubic feet per minute. In the airway there is a right angle bend and in coming against this bend the air is supposed to be brought momentarily to a standstill. Calculate the horse power lost. (15)

5. The air entering a deep dry mine is at all seasons completely saturated with moisture. At one season of the year the air entering is at 20 degrees F. and at another 80 degrees F. while the mine is at a constant temperature of 60 degrees F. Discuss the results, if any, affecting the safety of the mine due to these changes of temperature. (15)

6. If we have 25,000 cubic feet of air passing through an airway 5 feet by 6 feet, what quantity will pass through an airway 10 feet by 6 feet, pressure and length remaining the same? (15)

7. A pumping chamber in which works a steam pump has its only outlet to the upcast shaft. This shaft is 700 feet in depth and the pumping chamber is exactly half way down. Discuss fully how you would ventilate the chamber. (15)

Mine Manager's Examination.

Paper No. 3. Time Allowed, Three Hours.
The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Practical Work.

1. Is there any danger in the panel system of mining coal? Give reasons. (10)

2. Discuss the question of using coal cutting machinery under the various conditions under which coal is found in Alberta and show the advantage and disadvantages. (15)

3. Describe the general design of plant you would instal above ground to deal with a fairly large output of domestic coal and state the considerations governing your choice. (15)

4. Explain with the aid of sketches how the pressure of the overlying strata may be utilized in the getting of the coal. (15)

5. How would you proceed to open a mine after an explosion? (15)

6. How and of what material would you construct a dam in solid strata? What thickness of dam would you put in to withstand a head of 500 feet of water? (15)

7. Describe with sketches how you would work a flat lignite seam with a soft clay roof lying under 300 feet of cover. (15)

Mine Manager's Examination.

Paper No. 4. Time Allowed, Three Hours.
The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Machinery.

1. Sketch and describe the "Indicator." Draw a diagram taken from a condensing engine and point out the various features of the diagram. (12)

2. Explain fully the benefits of compounding engines and also the benefits of compressing air by different stages. (10)

3. What size ofp ump would you put in to pump 500 gallons of water per minute against a head of 300 feet? (15)

4. What are economizers as applied to boilers? Describe such an appliance. (12)

5. What are the various appliances which have been invented to prevent overwinding? Sketch and describe one of them. (15)

6. What size of hoisting engine would you put down to raise 800 tons of coal from a depth of 600 feet in 8 hours? (18)

7. What size of engine would you instal to work an endless rope haulage 6,000 feet long to deliver 800 tons in 8 hours hauling up a grade of 1 in 10? (18)

Mine Manager's Examination.

Paper No. 5. Time Allowed, Three Hours.

The value attached to each question is given in brackets. Candidates must obtain 60 per cent. of the allotted marks to pass.

Surveying.

1. Explain the difference between the transit and the miner's compass and discuss their respective uses in mine surveying. (10)

2. Plot the following survey and find the area of the enclosed figure:

Station.	Bearing.	Distance
1—2	N. 35.00 E.	147′
2—3	N. 59.15 E.	135′
3—4	S. 54.45 E.	237′
4—5	S. 36.15 W.	270′
5—2	N. 28.00 W.	323′

(20)

3. From a level, the course of which is N. 53.00 E. rooms are driven S. 68.00 E., width of room 28 feet and width of pillar 42 feet. What should be the distance on the level from centre to centre of rooms? (15)

4. If a triangle has one angle 61 degrees 10 minutes and another angle 62 degrees 15 minutes, what is the size of the third angle? (10)

5. Plot the following notes of a level book:

Back sight.	Intermediate sight.	Fore sight.	Distance in feet.
4.40	.....	6.35	230
5.20	.....	11.85	160
6.04	10.26	.....	190
.....	.....	13.95	180
5.12	.....	9.65	110
11.49	.....	4.92	225
13.96	7.50	.....	200
.....	.....	4.03	100

(20)

6. Explain the construction and use of the vernier as applied to surveying instruments. (15)

7. Draw to scale a mine car to hold one ton of coal when level full, mark on sides and show the car in plan, end elevation and side elevation. (10)

WAGES.

Fire bosses are still scarce although judging by the number of men coming up for examination for fire boss certificates the supply ought soon to reach the demand. In the early part of the year certain classes of mine workers obtained a slight increase in wages which increased scale is still maintained. The average coal diggers' wage, mining coal on contract, varies from $75.00 to $180.00 per month. The general wage schedule for day labor is as follows:

Inside Men.

		Hours.
Fire bosses	$3.50	8
Shot lighters	3.00	8
Bratticemen	3.00	8
Bratticemen helpers	2.50	8
Timbermen	3.00	8
Timbermen helpers	2.75	8
Drivers	2.75	8
Drivers, wet places	3.00	8
Team drivers	3.00	8
Tracklayers	3.00	8
Tracklayer helpers	2.75	8
Rock miners	3.50	8
Miners	3.00	8
Miners, wet places	3.50	8
Locomotive engineers	2.75	8
Switchmen	2.75	8
Chute loaders	2.75	8
Laorers	2.50	8

MINERAL WATERS.

Carbonate mineral waters, as agents in geologic changes, fall into two main subdivisions. Calcium is the important base in one, sodium in the other. Carbonic acid is usually present in sufficient quantity to form bicarbonates, thus making it possible for calcium, magnesius and iron to remain in solution. Upon evaporation calcium carbonate and magnesium carbonate are deposited, while ferrous bicarbonate is broken

up, and insoluble ferric oxide, or some insoluble hydroxide of iron, is formed by oxidation. The anhydrous resirue contains no bicarbonates except in some cases when sodium is predominant.

Carbonate waters carrying a relatively large proportion of silica are common. In volcanic waters, especially in geyser waters, the silica may reach half a gram to the litre, and sometimes even more. For instance, the waters of the Great Geyser, Iceland, carry 1,131 part sof solid per million. Of the total solids, silica constitutes 45.04 per cent.

PRODUCTION OF LEAD IN 1907.

Advance Statement by United States Geological Survey.

The total domestic production of refined lead in 1907, according to C. E. Siebenthal, of the United States Geological Survey, was 414,189 short tons, of which 314,241 tons was desilverized lead and 99,948 tons was soft lead. In 1906 the production of desilverized lead was 313,886 short tons; of soft lead, 90,783 tons; and the total refined lead was 404,669 short tons. The increase in production of 1907 over 1906 was therefore 9,520 short tons. The total for 1907 embraces all desilverized lead produced in this country and the pig lead recovered from the Mississippi Valley lead ores, but is exclusive of 9,910 tons of antimonial lead reported by refiners. Of the pig lead from Mississippi Valley ores, 29,809 tons were desilverized and are therefore not included under "soft lead."

The product of refined lead can not be apportioned according to the sources of ore from which it was derived, because the lead refineries treat also products that are secondary and are derived from diverse sources. The identity of ore, and thus its original source, is preserved only as far as the smelters. The following table, showing sources of lead produced in the United States, is therefore based on smelter figures. It includes "pig lead" reported by all known smelters running on Mississippi Valley lead ores and "lead" produced at all other known smelters in this country. No lead ores from the United States were treated elsewhere in 1907.

MANGANEZE ORES.

By E. C. Harder.

(Abstracted from Advance Chapter from Mineral Resources of the United States.)

Introduction.

The manganese-mining industry in the United States is at present, as for several years past, very small. In 1907 less than twenty manganese mines were in operation, and not half that number operated steadily. Of the large manganese districts of the United States, namely, the Valley and the Piedmont districts of Virginia, the Cartersville and the Cave Springs districts of Georgia, and the Batesville district of Arkansas, only the first two produced manganese ore in 1907. For this lack of activity there are three reasons—(1) the discontinuous and scattered nature of the deposits, (2) the crude mining methods naturally resulting therefrom, and (3) the low prices paid, which prevent attractive profits to operators under these conditions. All of the ore mined has to be either washed or sorted, and often both. Single pockets as a rule are small and are soon exhausted, so that the erection of expensive concentrating plants is discouraged, except in cases like the Crimora basin in Virginia, which is not at all typical of known American manganese deposits. In short, under present conditions domestic manganese can not compete with the foreign high-grade product. The larger part of the ore mined in this country was used in the brick, plant, and chemical industries, about one-sixth (947 long tons, valued at $6,747) being used in the steel industry, as against the 209,032 long tons imported for this purpose. The main reason for this seems to be that, although the demand in the former industries is limited, the prices paid are higher and ores can be used which would be undesirable in steel manufacture. Besides, the mining is on such a small scale that the supply does not run far ahead of the demand in these industries.

Uses.

The uses of manganese in the industries may be classified as follows: (1) Metallurgical, in the manufacture of alloys and in copper and silver reduction; (2) chemical, as an oxidizer and as a coloring material.

The manganese ores used in the manufacture of alloys are dependent in value on the percentage of metallic manganese present and on the absence of injurious substances like phosphorus and sulphur. The latter condition is especially true in the case of the alloys with iron. Spiegeleisen and ferromanganese are alloys of iron and manganese. The former contains below 20 per cent manganese, while the latter has a manganese content ranging from 20 per cent to 90 per cent, above which the alloy becomes unstable. Silicon and carbon are present in varying quantities. Spiegeleisen and ferromanganese are used in the manufacture of steel in the following ways—(a) as reducers of iron oxide in the final melting, in which case the manganese oxide formed goes into the slag; (b) as recarburizers of steel, in which case they contain considerable carbon; (c) for counteracting the effects of phosphorus and sulphur by the formation of manganese compounds with these elements; (d) in the manufacture of manganese steel, used for railroad and street-car rails on curves, for burglar-proof safes, for car wheels and for other purposes. The addition of small quantities of manganese gives to steel hardness, ductility and strength.

Manganese is also used to form alloys with copper, zinc, aluminium, tin, lead, magnesium, and silicon, and with combinations of these metals.

Manganese oxides are used to a slight extent in copper and silver reduction as a substitute for iron oxides.

As an oxidizer manganese oxide is used in the manufacture of chlorine, bromine, and oxygen, and of disinfectants like potassium permanganate; as a drier in paints and varnishes; as a decolorizer of glass, and in the Leclanche battery. In these cases the value of the ore depends on its available oxygen content—that is, on its percentage of pyrolusite or manganese peroxide.

As a coloring material manganese is used in calico dyeing; for coloring bricks, glass, and pottery, and in the manufacture of green and violet paints.

Compounds of manganese are used in a small way for medicine, and the mineral rhodonite, a silicate of manganese, is used rarely for ornamental purposes on account of its beautiful pink color.

Prices.

The prices of manganese ores used in the steel industry vary from $5 to $15 per long ton, according to the grade of the ore. They are governed by the following schedule of prices established by the Carnegie Steel Company:

Schedule of prices paid per ton of 2,240 pounds for domestic manganese ore delivered at Pittsburg or Bessemer, Pa., and South Chicago, Ill.

Prices are based on ores containing not more than 8 per cent silica or 0.25 per cent phosphorus, and are subject to deductions as follows: For each 1 per cent in excess of 8 per cent silica there shall be deduction of 15 cents per ton; fractions in proportion.

For each 0.02 per cent, or fraction thereof, in excess of 0.25 per cent phosphorus there shall be a deduction of 2 cents per unit of manganese per ton.

Percentage of metallic menganese in ore.	Price per unit, in cents. Manganese.	Iron.
Over 49	30	6
46 to 49	29	6
43 to 46	28	6
40 to 43	27	6

Ores containing less than 40 per cent manganese or more than 12 per cent silica or 0.27 per cent phosphorus are subject to acceptance or refusal at the buyer's option.

Settlements are based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken being deducted from the weight.

The manganese ores for oxidizing and coloring purposes are valued according to the quantity of manganese peroxide present, their consistency, etc., and prices range up to $25 per ton for the better grades of ore.

Production.

The production of manganese in 1907, amounting to 5,604 long tons, exceeded that of any year since 1902 except 1906. Toward the close of 1902 there occurred a sudden drop in production due to the cessation of mining operations in northwestern Georgia, after which there was a steady increase from the 2,825 tons produced in 1903 to 6,921 tons in 1906.

The bulk of the production was, as usual, in Virginia. South Carolina joined the ranks of producers for the first time since 1903, and produced more ore than in any previous year. Tennessee also showed an increase and a fair promise of becoming something more than a mere intermittent producer. California produced more ore than in any year since 1902. On the other hand, Georgia and Arkansas, which contain some of the most important manganese deposits in the country, were not on the list of producers of manganese in 1907, although Arkansas produced considerable manganiferous iron ore. The Utah mines, which gave fair promise for several years, were again idle.

OCCURRENCE.

Vermont.

Manganese ore occurs near the towns of South Wallingford and Brandon, in Otter Creek Valley, Vermont. In both localities the deposits are on the west slope of the Green Mountains at or near the contact of a "Lower Cambrian" quartzite, which forms ridges along the west slope, and an overlying limestone of approximately the same age, which underlies the valley to the west. The deposits are mainly brown hematite with subordinate manganese.

Virginia.

Manganese deposits occur in Virginia in the Piedmont region and in the Appalachian Valley.

The ore of the Piedmont region occurs in the James River Valley north and south of Lynchburg. There are a number of old mines in this district, but only one, that of the Piedmont Manganese Company, is at present producing. The deposits occur in residual clay and sand derived from ancient crystalline rocks. This material is still in place and often only partly decomposed, so that the texture and structure of the original rocks is clearly distinguishable. In general the ore occurs in nodular masses, ranging in weight up to 500 pounds and scattered through a yellowish-brown micaceous clay forming a nearly vertical layer between decomposed granite and quartzose mica schist residuum. The original nature of this ore-bearing layer is unknown.

Tennessee.

The manganese ores of Tennessee are the southward continuation of the Appalachian Valley deposits of Virginia. As in Virginia, they occur near the eastern border of the valley. The best known of the Tennessee deposits occur in the vicinity of Newport and Del Rio, Cocke County, and in Shady Valley, Johnson County.

The Yellow Springs mine, on English Mountain, 5 miles southwest of Newport, consists of an open pit in brown and red clays and sand, residual from Cambrian quartzite. The ore is both soft and hard, the former generally occurring in irregular pockets and seams associated with manganiferous clays, and the latter in small kidneys and irregular masses scattered through the clay and the soft ore pockets. There are numerous surface indications of manganese for several miles east of this mine, but little or no development work has been done.

Georgia.

Manganese ores occur in Georgia in three horizons: (1) The ancient crystalline rocks, (2) Weisner (Cambrian) quartzite, and (3) Knox (Cambro-Silurian) dolomite. The following is a general succession of rocks for northwestern Georgia from top to bottom: Knox dolomite; Conasauga shale; Beaver limestone; Weisner quartzite; Crystalline rocks.

In the crystalline area ores occur at Mount Airy, Habersham County; Bowersville, Hart County; Blue Ridge, Fannin County; and Draketown, Haralson and Paulding counties. All of these deposits are small, and none of them have been worked to any extent.

The ore is of four varieties: (1) Kidney ore, either amorphous, blue psilomelane, or a succession of concentric layers of psilomelane and crystalline and granular pyrolusite; (2) irregular masses, either psilomelane or a mixture of psilomelane and pyrolusite; (3) breccia and replacement ore with chert or sandstone fragments.

and (4) seams and irregular pockets of soft ore with local hard masses, a large portion of which must necessarily be lost during washing. The clays of the district are yellowish brown or red, according as they are derived from the Weisner quartzite or the Beaver limestone. The ores are generally associated with the former, and signs of manganese are present throughout the area covered by them, although only locally are there deposits rich enough to work. The breccia ores occur in residual sandstone or chert masses in the clays.

Arkansas.

Manganese ores of commercial importance have long been known in the Batesville district, in northern Arkansas. Smaller deposits occur in the southwestern part of the State, but these have not produced up to the present.

The Batesville district is located north of Batesville and east of Cushman, in Independence County. The country rock ranges from Cambrian to Carboniferous in age, and is in horizontal beds. The following is the general succession of rocks for the district:

General section in phosphate region of northern Arkansas.

Boone chert, St. Joe marble (Carboniferous).

Chattanooga shale and Sylamore sandstone (Devonian).

St. Clair limestone (Silurian).

Cason shale, Polk Bayou limestone, Izard limestone, Key sandstone (Ordovician).

Manganese ores occur in three different associations in the Batesville district, but all of them at very nearly the same geological horizon, namely, between the Boone chert and the Polk Bayou limestone, or locally the Izard limestone, where the Polk Bayou is absent. (1) The Cason shale locally becomes red and sandy and contains an abundance of small lenticular manganiferous iron nodules constituting a low-grade manganiferous iron ore deposit. This bed where exposed is 10 feet or more in thickness. (2) In most of the mines of the district the horizon normally occupied by the formations given above, between the Boone chert and the Polk Bayou limestone, is occupied by a manganese-bearing bed of varying nature, which appears to be partly residual from the erosion of other rocks formerly occupying this horizon and partly deposition of new material. This bed is also called the Cason shale, and although occupying a wider horizon is presumably equivalent to (1). It varies in thickness from a few inches to many feet because of the irregular surface of the underlying Polk Bayou limestone. The formation consists sometimes of clay with manganese ore fragments, sometimes of a solid bed of sandy, low-grade ore with associated sediments, and at other times of partial replacement of sediments. (3) The remaining forms of manganese deposits are associated with residual clays on the slopes of hills below the main manganese horizon above mentioned. These deposits consist of masses of psilomelane, pyrolusite, and braunite, and are reconcentrations from the manganese bed above. Only one mine in the district, the Cason, was a producer in 1907, but several deposits have been worked recently, among them the Reeves, Bales, Roach, and Meeker mines. The principal old mines are the Southern, Polk-Southerd, Turner, Adler, Trent, Baxter, and Montgomery mines.

COKE MAKING IN VIRGINIA.

As a result of the financial stress during the closing months of 1907, the production of coke in Virginia was less by 32,379 short tons, or 2.1 per cent. than in the preceding year, amounting to but 1,545,288 short tons in 1907, as against 1,577,659 short tons in 1906, according to E. W. Parker, chief statistician of the United States Geological Survey, whose report on the manufacture of coke in 1907 is now in press. Owing, however, to the better prices that prevailed during the greater part of the year, the value of the coke produced in 1907 shows an increase of $154,074—from $3,611,659 in 1906 to $3,765,733 in 1907. The number of establishments increased from 18 in 1906 to 19 in 1907, and the total number of ovens from 4,641 in the earlier year to 5,333 in the later. One establishment of 400 ovens was idle throughout the year. All of the coal used in the manufacture o fcoke in Virginia in 1907—2,264,720 tons—was unwashed; 1,271,518 tons was run-of-mine and 993,202 tons slack.

All the coking coals of Virginia are contained within a few counties in the extreme southwestern portion of the State, the coal fields being within the Appalachian province. The greater part of the development which has resulted in actual production during the last few years has been carried on in Wise County, on the Clinch Valley branch of the Norfolk and Western Railway. The coke in this district is the only coke made at the present time from coal mined exclusively within the State. There are two plants in Virginia, one at Lowmoor and one at Covington, the coal for which is drawn from the mines in the New River district of West Virginia. The coal for the ovens at Pecahontas and part of the Flat Top district of Tazewell County is obtained from mines whose workings extend across the State boundary line into West Virginia, and a part of this coal production should properly be credited to West Virginia. The openings of the mines, however, and the coke ovens are in Tazewell County, and it is customary to credit the coal as well as the coke to Virginia. The total production of coke in Wise County in 1907 amounted to 1,353,225 short tons, or 87.6 per cent of the total for the State.

It seems probable that the development work that has been in progress in the Black Mountain region of Lee County and in Wise County during the last few years will before long result in marked increase in the coke production of Virginia.

MOLYBDENUM.

Molybdenum is one of the rarer metals. It is most frequently found in granite in the form of the sulphide, molybdenite. The molybdates of iron, calcium, and lead, are also known as mineral species. Molybdenite often appears as a primary mineral in igneous rocks.

Molybdenite, the sulphide, is the principal ore of molybdenum. Wulfenite, the molybdate of lead, is a rare material; so also is powellite, calcium molybdate.

Molybdenite is usually a fairly pure compound, although a variety carrying 28.37 per cent. bismuth has been found, evidently a mixture of molybdenite and bismuthinite. In Canada molybdenite occurs in granite but also in veins cutting limestone and associated with pyroxene, calcite, quartz, mica, pyrite, etc.

BOOK REVIEWS.

GOLD AND SILVER.—Comprising an Economic History of Mining in the United States, etc. By Walter R. Crane, Ph.D., Instructor in Mining, School of Mines, Columbia University. 8 vo., X + 727 pages, illustrated. Cloth, $5 net (21s. net). John Wiley & Sons, New York.

The preparation of this work occupied two years. It is intended to form a part of the Economic History of the United States, which is to be published by the Carnegie Institution of Washington. Special permission was granted by the authorities of that institution to the author whereby publication of this volume was made possible.

The economic history of the precious metals is a subject at once complicated and extensive. The student is led into many by-paths. The halo of romantic interest that pertains to the earlier days of gold and silver mining must be a standing temptation to any writer.

However, Dr. Crane sticks manfully to his course.

Chapter I. delineates the bearing of precious metal mining upon the industrial growth of the United States. One sentence in this chapter, touching the relation of transportation facilities to mining development, has caught our eye:—"Gibbons regarded the Romans as the most remarkable road builders of the world, but the people of California had in fifty years done more road building within the confines of their State than had the Romans in their entire empire in fully ten centuries."

Chapter II. is an historical account of the discovery of gold and silver, followed by sketches of recent history of mining in each of the producing states and territories. The chapter concludes with a chronology of gold and silver mining.

Chapter III., on the occurrence and association of gold and silver, is a concise and useful summing up of the theory of ore formation, and the actual vein occurrences in the various states, etc. Gold in granite is given similar treatment.

In Chapter IV. the geological distribution of gold and silver is considered. Chapter V. deals, historically and descriptively, with the several methods of gold and silver ore mining. Chapter VI. takes up the extraction of the metals from their ores. The chapter is entitled "Extraction of Values." Mr. T. A. Rickard has alluded to the inaptness of word "values" when it is used in this sense. Here it is obvious that the word "metals" would be far more suitable.

Chapter VII. is mainly statistical.

Useful data are presented in tabulated form in six appendices. Diagrams and half-tones are interspersed throughout the text.

In addition to interesting material collected and used, and the satisfactory manner in which it is presented, we wish to commend particularly the plan of this work. The volume has a well articulated backbone.

LEAD AND ZINC IN THE UNITED STATES.—Comprising an Economic History of the Mining and Smelting of the Metals and the Conditions Which Have Affected the Development of the Industries. By Walter Renton Ingalls, Editor of the Engineering and Mining Journal. Illustrated. Cloth, 6⅛ x 9 ⅛. 368 pages. Price, $4 net. Hill Publishing Company, New York, 1908.

The author, than whom few are more competent to attack the subject, has endeavoured to describe the economic influences that have contributed to the development of the lead and zinc mining and smelting industries in the United States. But brief mention is made of early discoveries; but the economic forces, called into play by the growth of the nation and by modern requirements, are adequately outlined.

The book was prepared at the request of the Carnegie Institution of Washington, and with its assistance. It is to form a part of the Economic History of the United States, which is to be published by the Carnegie Institution.

In his introduction the author gives us a glimpse of the history of lead and zinc mining in the United States. "Up to 1901 it might have been possible to consider independently the lead and zinc industries of the United States, but from the economic standpoint it will never more be possible to do so."

From 1720 to 1820 the total production of lead amounted to about one-seventh the output of a single year at the beginning of the twentieth century. Southeastern Missouri was, up to 1821, the principal producer. From that year on to 1870, Wisconsin played the leading part. Since 1871, Utah, Nevada, Colorado and Idaho have become prominent.

Zinc was first made in the United States about 1838. It was produced from the red zinc ore of New Jersey, for use in the preparation of brass for standard weights and measures ordered by Congress. The process was not commercially profitable. Richard Jones, in 1850, began the manufacturing of zinc at Newark, N.J., but failed to make it pay. In the succeeding year Samuel Wetherill produced zinc oxide direct from the ore, on a commercial scale. In 1860 spelter works were put in successful operation. The Joplin mines became productive in 1873, and now are responsible for the greater part of the United States output.

Chapter I. deals with the occurrences of lead ore in the producing districts of the United States. Many useful facts have been compressed into this chapter. Chapter II. is a chronology, presenting the outstanding events in the history of lead mining. After the first date, 1621, is the following record:—"Lead was mined and smelted near Falling Creek, Va., to supply the local demand for bullets and shot. This was the first mining and smelting of lead in what is now the United States." After the last date, 1906, comes a paragraph that forms a striking contrast:"The Guggenheim interests practically secured control of the National Lead Company, thus bringing the major part of the lead-consuming industry of the United States into direct affiliation with the American Smelting and Refining Company."

Chapter III. is a strong and complete outline of the metallurgy of lead. Then follows a section on refining, marketing, and uses, after which the producing States are taken up in detail. Statistics of production, consumption, and prices, commercial conditions, the tariff on lead, labour and trade conditions, trade combinations, are the subjects of the concluding chapters of Part I., which comprises more than two-thirds of the volume.

Part II. treats the zinc industry in the same manner.

Mr. Ingall's point of view is wide and comprehensive, while his intimate knowledge of lead and zinc mining and smelting enables him to write profitably on the technical phases of his subject, his broad grasp of commercial conditions has made possible the excellent chapters on the economic phases. The plan followed has been wisely conceived and skillfully executed.

THE ANALYSIS OF ASHES AND ALLOYS. By L. Parry, A.R.S.M., Assayer and Consulting Metallurgist. 143 pages...Price 5s. net. .Published by "The Mining Journal," 46 Queen Victoria Street, London E. C., 1908.

Although of wider scope than indicated by its title, this book is intended to meet first the requirements of those who have to deal with "all sorts of complicated metalliferous mixtures . . . ashes, drosses, scrap, fume, precipitate, slag, etc."

Section I. embraces the determination of individual metallic elements; Section II., the analysis of various "ashes," or metalliferous residues; Section III. comprises a summary of methods and a descriptive list of chemicals, standard solutions, etc.

"Analysis of Ashes and Alloys" will be found most serviceable by practicing analysts. It is not intended for the instruction of beginners, nor for class-room use. The author's aim has been to condense a complete summary of his subjects into as brief form as practicable.

COAL. By James Tonge. 275 pages. Price, $2 net. D. Van Nostrand Company, 23 Murray and 27 Warren Streets, New York, 1907.

As a general introduction to a fascinating subject, Mr. Tonge's new book will, we think, serve a useful purpose.

There are many controversial and debatable points in the study of the origin, classification, and uses of coal. Many of these are touched upon by the author. The space limitations of a small elementary volume preclude the possibility of discussing these questions, and the author must, perforce, become somewhat dogmatic. Hence the reader may be given impressions that will be changed by later reading. This, however, is an unavoidable feature of nearly all elementary treatises.

The history, occurrence, mode of formation, paleobotany, classification, valuation, uses, waste, preparation for market, are among the subjects treated interestingly. Both British and foreign coal-measures are described. The economic and geographical importance of the world's coaling stations is treated. The book is well illustrated.

THE GEOLOGY OF COAL AND COAL-MINING.—By Walcot Gibson, D.Sc., F.G.S. Pages 341. Illustrated. Price 7s. 6d. net. Edward Arnold, 41 and 43 Maddox Street, London, W. 1908.

This is the first of a series of works on economic geology, to be published by Edward Arnold.

There is no study that has been more generally neglected than economic geology; and there is none that so little deserves this neglect. The prodigal waste of the world's mineral resources may justly be credited to our ignorance as nations and individuals of the necessity of conserving those resources.

Education by means of such books as Dr. Gibson's is the best and most direct means of awakening the public to the importance of developing wisely and utilizing sanely our mineral deposits. The general diffusion of a knowledge of economic geology is, therefore, the best preventive of waste and the most effective remedy for indifference.

The first chapters of the book take up the chemical, geological, and paleontological characteristics of coal. These are succeeded by chapters of much practical value, on prospecting and investigation. The coalfields of Great Britain then receive detailed attention, and in conclusion the coalfields of both hemispheres are describe dbriefly.

Throughout the volume, the close relation of geology to mining is impressed upon the reader. The interpretation of fossils is not neglected. Two particularly good chapters are given on the study of "exposed" and of "concealed" coalfields.

We have no hesitation in commending this excellent little volume.

EXCHANGES.

The Colliery Guardian, August 7, 1908.—The British Home Office some time ago appointed Mr. Ernest Aves to investigate the workings of the Wages Boards and Industrial Conciliation and Arbitration Acts of Australia and New Zealand. The Colliery Guardian describes Mr. Aves' report upon these subjects as being of great value.

These efforts at industrial legislation, remarks our contemporary, have been the result of a sincere desire to maintain a fair wage and to preserve industrial peace. They are fairly open to criticism because they are first attempts to meet a complicated industrial situation and because they have not been in service long enough to have lost their first imperfections.

Mr. Aves found that the original acts are in constant process of amendment to meet difficulties that are only revealed by actual working. Dissatisfaction on the part of employers and employees was evident everywhere. Nevertheless public opinion is increasingly opposed to a reversion to former methods of settlement of industrial difficulties and there is "a growing tendency in favor of facilitating voluntary agreements, and, failing these, of compulsory reference to a third party for investigation and report."

"The whole theory of compulsory arbitration," continues the Guardian, "stands or falls by the power of the Government to enforce its awards. This is where the New Zealand act has proved a lamentable failure." In the case of the Blackball coal mine, the miners openly defied the law because the award was not to their liking. The men remained on strike for two months after the dispute had been compulsorily settled, and the fines have not yet been collected by the sheriff. In this instance the law-breakers had the support of labor unions all over New Zealand.

Mr. Aves' conclusion is that the industrial disputes legislation in New Zealand and Australia has not been sufficiently successful to be taken as a model in other countries.

PERSONAL AND GENERAL.

Mr. R. R. Hedley, formerly of Hedley, B.C., visited Sudbury about the middle of August.

Mr. W. Dixon Craig, mine examiner for Drummond Mines, Limited, passed through Toronto on August 15.

Mr. G. F. Vasey, eastern representative of Jacques, Baszanger & Co., importer of diamond drill carbons and bortz, passed through Toronto on his way to Sudbury on August 21.

The Hon. William Templeman, Minister of Mines, accompanied by Mr. Reginald W. Brock, acting director of the Geological Survey, is visiting the mining districts of British Columbia.

Mr. John Kerr, the discoverer of the Tilbury oil field, died at Detroit on the morning of August 17, at the age of 45 years. Mr. Kerr sunk the first well on his own farm and had the courage to stick to the work in the face of ridicule and indifference.

Mr. John Ashworth, president of the Manchester Geological Society, has been spending some weeks in Canada. He will join the summer excursion of the Canadian Mining Institute on September 3 at Toronto. Ten years ago Mr. Ashworth examined and reported upon the Wright lead mine on Lake Temiscamingue.

Mr. Edmund B. Kirby, manager of the Federal Lead Company, Flat River, Mo., will retire on October 15th next, and devote his time thereafter to consulting work with headquarters at 701 Security Building, St. Louis, Mo. His successor to the management is to be Mr. H. A. Guess, who is at present milling superintendent of the American Smelters Securities Company.

INDUSTRIAL SECTION.

Solignum—Wood Preservative.—Solignum is a preservative for wood, stone and brickwork. It protects against decay, fungus, dry rot, insects and vermin, and the action of the weather. Solignum is not only a preservative, but a stain also. A gallon will cover 250 to 350 square feet. It does not increase the inflammability of the wood. For lengthening the life of all wooden structures and implements solignum has been used all over the world with excellent results. It is of especial service in preventing the decay of mine timbers. Its value in this respect deserves the attention of Canadian mining men. The British Agencies Company, 32 Church street, Toronto, are the sole agents for Canada.

Bulletin No. 27.—Improved Huntington Mills.—Power and Mining Machinery Company, Cudahy, Wis., U. S.A.

The Hutington mill is a centrifugal roller crusher and grinder. It can be used in place of stamp mills wherever hard or soft rock is to be reduced to a fineness of from 20 to 8 0mesh, but it is especially designed for crushing clayey ores and for the reduction and amalgamation of gold and silver ores.

While resembling the Cornish rolls in certain respects, the Huntington mill differs in that the rolls are set vertically and that they work in water. The advantages claimed for it are:

1. Low cost of machine.
2. Low freight charges.
3. Low cost of installation.
4. Easily accessible and cheaply replaceable wearing parts.
5. Low consumption of power.
6. Large discharge area, quick delivery, and minimum sliming.
7. Clean and efficient amalgamation.
8. Simplicity of construction and operation.

The 3′ 6″ Huntington should not be fed with ore larger than ½″ in diameter. The 5′ and 6′ machines can handle rock as large as 1″. But on account of the high speed at which the rollers are driven, the material fed should be as fine as practicable, and when coarse ore is fed the machine should be slowed.

The improvements effected by the Power and Mining Machinery Company are briefly these: In place of the wood frame for supporting the mill, a heavy cast iron base is supplied. This presents loss of alignment and does away with vibration.

The countershaft bearing is supported by a heavy bracket which is an integral part of the base.

The mortar has been strengthened all over and the centre cone is fitted with removable phosphor bronze bushing. The curb is a heavy casting made in halves securely bolted together and also batted by heavy through bolts to the motar and base. The shafts and roller spindles are forged from mill steel and are extra heavy. The gearing is cast from semi-steel and is extra heavy.

The roller heads are bored full length and have a large recess for lubricant on top. The scrapers are made reversible and of hard white iron, and are so shaped as to pick up readily the pulp from the bottom and throw it against the ring-die.

These and other improvements give color to the claims of the manufacturers.

The 3½″ Huntington mill is sectionalized for mule-back transportation. A rigid yoke with two bearings for the countershaft and a seat for the stepbox is substituted for the base casting.

Useful working diagrams of complete Huntington mill plants are included in the Bulletin.

The Grand Trunk Railway System have placed an order for a ten-ton hand power travelling crane with the Smart-Turner Machine Company, Limited, to be placed in their shops at Stratford.

The Smart-Turner people are also supplying an automatic feed pump and receiver for the heating system of Lansdowne school, Toronto.

Fourteen persons were killed and one injured in an explosion at the Washington "Glebe" Colliery, Durham, England, on February 20, 1908. The seam where the explosion occurred was moderately dusty and the workings were dry. The permitted explosive, Bellite No. 1, was used and fired by electric battery. The report of an investigation that followed the accident recommends that the necessity of further precautions be considered: (a) The necessity of shot-firers understanding fully all the conditions of danger, (b) the provision of some more satisfactory means of testing for fire damp; (c) the removal of any doubt on the subject of watering, removing or otherwise rendering harmless, coal dust on the floor of working places before shots are fired.

LIST OF CANADIAN OPERATING MINING COMPANIES

COMPILED SPECIALLY FOR THE CANADIAN MINING JOURNAL.

NOVA SCOTIA.

NOVA SCOTIA GOLD MINING COMPANIES.

Boston-Richardson Mining Company, Isaac's Harbour, Guysboro county.
Beaver Hat Golding Mining Company, Lower Seal Harbour, Guysboro county.
McDonald and Copeland, Forest Hill, Guysboro Co.
California Gold Mining Company, Cochran Hill, Guysboro county.
Wine Harbour Gold Mining Company ,Wine Harbour, Guysboro county.
Harrigan Cove Gold Mining Company, Harrigan Cove, Halifax county.
Dominion Mining Company, Tangier, Halifax county.
J. H. Anderson, Lake Catcha, Halifax county.
Oxford Gold Mining Company, Lake Catcha, Halifax county.
F. W. Hanwright, Lake Catcha, Halifax county.
Dixon Mine, Caribou, Halifax county.
Baltimore and Nova Scotia Mining Company, Caribou, Halifax county.
Consolidated Mines of Canada, Limited, Moose River, Halifax county.
Nova Scotia Gold Mines, Montague, Halifax county.
Chester Basin Gold Syndicate, Gold River, Lunenburg county.
Reardon Reeves Property, Gold River, Lunenburg Co.
Micmac Gold Mining Company, Leipsigate, Lunenburg county.
Eagle Mining Company Renfrew, Hants county.
Great Bras d'Or Gold Mining Company, Middle River, Victoria county.

GYPSUM.

The following is a list of those engaged in this very important industry:
The Wentworth Gypsum Company, Windsor.
The Victoria Gypsum Company, St. Anns, C.B.
The Maritime Gypsum Company, Amherst.
The Windsor Gypsum Company, Windsor.
The Nova Scotia Gypsum Company, Three Mile Plains.
Albert Parsons, Walton and Cheverie.
W. B. O'Brien, Noel.
Lorenzo Ettinger, Noel.
Lewis M. Smith, Cheverie.
George Hamilton, Noel.

PRINCIPAL OPERATING COAL MINES OF NOVA SCOTIA.

Dominion Coal Company, Glace Bay, C.B.
Nova Scotia Steel Company, Sydney Mines.
Cumberland Railway and Coal Company, Springhill, N. S.
Fundy, Lower Cove, N.S.
Port Hood Coal Company, Port Hood, C.B.
Inverness Railway and Coal Company, Inverness, C.B.
Mabou and Gulf Coal Company, Mabou Mines, C.B.
Joggins, Joggins, Cumb., N.S.
Scotia Coal Company, Maccan, Cumb., N.S.
Minudie Coal Company, River Hebert, Cumb., N.S.
Acadia Coal Company, Stellarton, N.S.
Nova Scotia Steel Company, Marsh Colliery, N.S.
North Atlantic Collieries, Port Morien, C.B.
Strathcona Coal Company, River Hebert, Cumb., N.S.
Gowrie Block House Company, Port Morien, C.B.
Sydney Coal Company, North Sydney, C.B.
Cape Breton Coal Company, New Campbellton, C.B.
MacKay Coal Company, North Sydney, C.B.
Chignecto, Chignecto, Cumb., N.S.
Intercolonial Company, Westville, N.S.

IRON.

Londonderry Iron & Mining Company, Torbrook, N.S.
Dominion Iron & Steel Company, Sydney, N.S.
Nova Scotia Steel & Coal Company, New Glasgow, N.S.

COPPER.

The Colonial Copper Company, Cape d'Or, N.S

ONTARIO.

ONTARIO MINES.

List of mining companies who make yearly returns to the Bureau of Mines:

ARSENIC FROM MISPICKEL ORE.

Canadian Gold Fields, Limited, Deloro, Ont.
Atlas Arsenic Company, Deloro.
Major R. G. Leckie, Sudbury.
Temagami Mining and Milling Company, Limited, Charles L. Beckwith, Pres., 346 Broadway, New York.

ACTINOLITE.

American Asbestos Company, New York.
International Asbestos Company, Ralph H. Waggoner, Pres., 309 Broadway, New York.

PORTLAND AND NATURAL ROCK CEMENT.

Belleville Portland Cement Company, Belleville.
Canadian Portland Cement Company, Marlbank.
Imperial Cement Company, Limited, Owen Sound.
Hanover Portland Cement Company, Limited, Hanover.
Lakefield Portland Cement Company, Limited, Lakefield.
National Portland Cement Company, Limited, Durham.
Owen Sound Portland Cement Company, Limited, Owen Sound.
Ben Allen Portland Cement Company, Limited, Owen Sound.
Superior Portland Cement Company, Limited, Orangeville.
Western Ontario Portland Cement Company, Limited, Atwood.
Ontario Portland Cement Company, Limited, Brantford.
Colonial Portland Cement Company, Limited, Wiarton.
Grey and Bruce Portland Cement Company, Limited, Owen Sound.

Sun Portland Cement Company, Limited, Owen Sound.
Estate of John Battle (Natural Rock), Thorold.
F. W. Schwendimann Cement Works, Limited, Hamilton.
Toronto Lime Company, Limited, 34 Yonge street, Toronto.
I. Usher & Sons Cement Works, Limited, Queenston.

GOLD.

St. Anthony Gold Mining Company, A. L. McEwen, Ignace, Ont.
Redeemer Mining and Milling Company, Gust. Larson, Mgr., Dryden, Ont.
Golden Reed Mining Company, Menso Gates, Pres., 402 Carrie street, Sault Ste. Marie, Mich.
Argenteuil Gold Mining and Milling Company, Limited. J. W. Lewis, Secy., Saginaw, Mich.
Rush Bay Golden Horn Mining Company, A. McMeekin, Box 24, Kenora, Ont.
Magpie Gold Mining and Development Company, Limited, Chas. M. Sayles, Secy., Sault Ste., Marie, Mich.
Camp Bay Mining Company, W. C. Penpz, DuBois, Pa.
Volcanic Reef Gold Mining Company, Limited, W. A. McBernie, Cannonsburg, Pa.
Detola Development Company, Chas. J. Rescher, Sec.-Treas., 919 Nicolas Bldg., Toledo, Ohio.
Olympia Gold Mining Company, Limited, Geo. H. Vernon, Secy., 308 National German-American Bank Bldg., St. Paul, Minn.
English River Gold Mining Company, Limited, James N. Walker, Secy., St. Catharines, Ont.
Imperial Gold Mines, Limited, Anthony Blum, 43 Tremont St., Boston, Mass.
Empire Gold Mining and Milling Company, Herman B. Singer, 375 Williams St., Buffalo, N.Y.
The Regina Gold Mine, Lt.-Gen. Sir Henry C. Wilkinson, K.C.B., Kenora, Ont.
Northern Light Mines Company, W. H. Barnhart, Secy., 629 Prudential Bldg., Buffalo, N.Y.
Big Dipper Mining and Milling Company, Limited, J. S. Waldron, Secy., 3771½ George St., Peterboro, Ont.
Ideal Gold Mining Company, Wm. Johnston, 109 Charlotte Ave., Detroit, Mich.
Craig Gold Mining and Reduction Company, H. B. Whitney, Pres., Phelps, N.Y.
Shakespeare Gold Mining Company, Limited, B. W. Dunn, Pres., Webbwood, Ont.
The Grace Mining Company, Limited, Andrew Holz, Secy., 872 Ellicott Sq., Buffalo, N.Y.
Sultana Gold Mining Company, Limited, John F. Caldwell, Director, Winnipeg, Man.

GRAPHITE.

The Ontario Graphite Company, Limited, Rinaldo McConnell, 175 Cooper St., Ottawa, Ont.
The Globe Refining Company, Limited, Rinaldo McConnell, 175 Cooper St., Ottawa.
J. G. Allan, 211 Bay St. S., Hamilton, Ont.

IRON.

Wilbur Iron Ore Company, Limited, F. V. Clisdall, Secy., 308 Stair Bldg., Toronto.
The Lake Superior Power Company, Sault Ste. Marie, Ont.
Mineral Range Iron Mining Company, Limited, H. L. Bingham, Secy., Bessemer, Ont.
The Breitung Iron Company, Edward N. Breitung, Sec.-Treas., Marquette, Mich.
Atikokan Iron Company, Limited, Fred Rodda, Port Arthur, Ont.
T. B. Caldwell, M.P., Lanark, Ont. (Calibogie Iron Mine.)
Williams Iron Mines, Limited, Chas. C. Williams, Secy. and Gen. Mgr., Sault Ste. Marie, Mich.
Canada Iron Furnace Company, Limited (Radnor Mine), J. M. Roy, Canada Life Bldg., Montreal.

IRON PYRITES.

The Nichols Chemical Company of Canada, Limited, C. U. Nichols, Pres., 25 Broad St., New York.
Lake Superior Power Company, Sault Ste. Marie, Ont.
Canadian Pyrites Company, Felix A. Vogel, 25 Broadway, New York.
Northern Pyrites Company, John Webb, Jr., Supt., Dinorwic, Ont.
Northland Mining Company, Limited, John Smallman, Secy., London ,Ont.

CALCIUM CARBIDE.

Ottawa Carbide Company, Ottawa, Ont.
Wilson Carbide Works, St. Catharines, Ont.

COPPER.

Massey Station Mining Company, Massey Station, Ont.
Consolidated Copper Company, Limited, Parry Sound.
Superior Copper Company, Sault Ste. Marie, Mich.
International Gold and Copper Company, Limited, 433 Mooney-Brisbane Bldg., Buffalo, N.Y.
Parry Sound Copper Mining Company, Otto Monson, Secy., St. Paul, Minn.
Martin Pattison & Co., Superior, Wis.
Black Bay Mining Company, N. B. Carlson, Secy., Willmar, Minn.
Calumet and Sault Ste. Marie Development Company, N. F. Kaiser, Secy., Calumet, Mich.
Hermina Mining Company, S. H. Bryant, Mgr., Massey Station, Ont.
Calumet & Algoma Mining Co., Lucas Herman, Secy., Calumet Mich.
Tip-Top Copper Mine, S. W. Ray, Port Arthur, Ont.
Madina Copper Company, Col., Cole Saunders, Pres., Eldorado, Ont.
Northern Ontario Consolidated Copper Company, T. E Crawford, Secy., Sault Ste. Marie, Ont.
The Cobden Mining Company, Sault Ste. Marie, Ont.

CORUNDUM.

Canada Corundum Company, D. A. Brebner, Secy.-Treas., 23 Scott St., Toronto.
The Ashland-Emery Company, Burgess Mine P.O., Ont.

FELDSPAR.

Kingston Feldspar Mining Company, Kingston, Ont.
Verona Mining Company, 706 Girard Trust Bldg., Philadelphia, Pa.
Charles Jenkins Feldspar Mine, Tishborne, Ont.

LIST OF OPERATING MINES AT COBALT

Standard Cobalt Mines, Limited, Thomas J. Maloney, Treas., 37 Wall St., New York.
Coniagas Mines, Limited, J. J. Mackan, Secy., St. Catharines, Ont.
Right of Way Mining Company, Limited, E. A. Larmouth, Secy.-Treas., Central Chambers, Ottawa.
Trethewey Silver Cobalt Mining Company, Limited, D. A. Brebner, Secy., 1428 Traders Bank Bldg., Toronto.

Buffalo Mines, Limited, Geo. C. Miller, 1012 Fidelity Bldg., Buffalo, N.Y.
Cobalt Silver Queen Mining Company, Limited, J. H. Stephens, Secy., 730 Traders Bank Bldg., Toronto.
Temiskaming and Hudson Bay Mining Company, Limited, F. L. Hutchinson, Secy., New Liskeard.
McKinley-Darragh-Savage Mines, W. L. Thompson, Treas., 100 Sibley Block, Rochester, N.Y.
Nipissing Mining Company, Limited, F. S. Whitworth, Cashier, Cobalt, Ont.
O'Brien Mine, Fred W. Rouse, Secy.-Treas., Cobalt.
Foster Cobalt Mining Company, Limited, Geo. Foran, Home Life Bldg., Toronto.
Colonial Mining Company, Limited, G. W. McCaskell, Mgr., Cobalt.
Kerr Lake Mining Company, J. A. Jacobs, 171 St. James St., Montreal.
Drummond Mines, Limited, J. Gouldthorpe, Acct., 70 Canada Life Bldg., Montreal.
Silver Leaf Mining Company, Limited, D. F. Maguire, Secy., 18 King St. W., Toronto.
Silver Bar Mining Company, Limited, J. H. Hubbell, Supt., Box 531, Cobalt.
Temiskamingue Mining Company, Limited, Norman R. Fisher, Gen. Mgr., Cobalt, Ont.
Cobalt Townsite Mining Company, Limited, B. W. Leyson, Supt., Cobalt, Ont.
Nancy Helen Mining Company, Limited, J. F. Black, Mgr., Cobalt.
Green-Meehan Mining Company, Limited, J. G. Langton, Secy., 28 Manning Arcade, Toronto.
Cobalt Lake Mining Company, Limited, D. B. Rochester, Man. Dir., Cobalt, Ont.
Crown Reserve Mining Company, Limited, J. Carson, Pres., Royal Bldg., Montreal, Que.
Chambers-Ferland Mining Company, Limited, Haileybury, Ont., Alex. Fasken, Secy., Toronto.
King Edward Silver Mines, G. W. McCaskell, Mgr., Cobalt, Ont.
La Rose Consolidated Mines Company, B. E. Rodden, Auditor, Cobalt, Ont.

LEAD.

Ontario Mining and Smelting Company (Holandia Mine), Chas. B. Wolfe, Treas., Fuller Bldg., New York.
The Stanley Smelting Works, R. E. Cushman, Secy.-Treas., Perth Road, Ont.

PETROLEUM.

Imperial Oil Company, Sarnia, Ont.
Canadian Oil Refining Company, Limited, B. Dunlop, Supt., Petrolia, Ont.
The Union Oil Company, Limited, W. P. Bull, Holiss & Wilson, Temple Bldg., Toronto.
Rainsberry & Co., Sarnia.

COPPER-NICKEL.

Canadian Copper Company, Copper Cliff, Ont. (International Nickel Company).
Mond Nickel Company, C. V. Corliss, Mine Supt., Victoria Mines, Ont.

PRESSED BRICK AND TERRA COTTA.

Beamsville Brick and Terra Cotta Company, G. Crain, Secy., Beamsville, Ont.
Don Valley Brick Company, Toronto.
Toronto Pressed Brick and Terra Cotta Company, Milton, Ont.
Port Credit Brick Company, Port Credit.
Brampton Pressed Brick Company, Brampton.
Ontario Paving Brick Company, Limited, West Toronto.
Terra Cotta Pressed Brick Company, Alfred Cornwell, Gen. Mgr., 1070 Bathurst St., Toronto.
Milton Pressed Brick Company, Limited, Milton.

SEWER PIPE.

W. J. Anthutle, 309 Cromwell St., London, Ont.
F. D. McFie, 316 Bunnell St., London, Ont.
Hamilton and Toronto Sewer Pipe Company, 77 York St., Toronto.
Dominion Sewer Pipe Company, Swansea, Ont.
Ontario Sewer Pipe Company, Limited, 60 Victoria St., Toronto.

SALT WORKS.

E. S. Henderson, Canadian Salt Company, Limited, Windsor.
Parkhill Salt Company, Parkhill, Ont.
Messrs. R. & J. Ransford, Clinton.
The Gray, Young & Sparling Company, Wingham, Ont.
George McEwan Salt Works, Hensall, Ont.
Exeter Salt Works Company, Exeter.
J. Tolmie, Ontario People's Salt and Soda Company, Limited, Kincardine.
Peter McEwan Salt Works, Goderich.
Carter & Kittermaster Salt Works, Moooretown.

TALC.

A. A. Robbins Mining Company, Chris. Henderson, Madoc, Ont.
Stephen Wellington, Madoc, Ont.

BLAST FURNACES.

Hamilton Steel and Iron Company, H. H. Champ, Secy., Hamilton, Ont.
Deseronto Iron Company, F. B. Gaylord, Mgr, Deseronto, Ont.
Canada Iron Furnace Company, J. J. Drummond, Midland, Ont.
The Algoma Steel Company, Limited, J. S. Wynn, Gen. Auditor, Sault Ste. Marie, Ont.
Ontario Iron and Steel Company, Welland.
Atikokan Iron Company, Port Arthur, Ont.

QUEBEC.

List of companies in the Province of Quebec in operation, or in position to work, with their addresses:

MAGNETIC SAND.

Quebec Iron Ore Company, 75 St. Peter St., Quebec.
H. C. Bosse, 112 St. Peter St., Quebec.
W. Robertson, 233 St. James St., Montreal.

CHARCOAL PIG IRON.

Canada Iron Furnace Co., The, Canada Life Bldg., Montreal.
John McDougall & Co., 597 William St., Montreal.

TITANIC IRON.

G. Gagnon, 87 Artillery St., Quebec.

OCHRE.

Canada Paint Company, Limited, 572 William St., Montreal.
Champlain Oxyde Company, Lucien Carignan, Three Rivers.
Thomas Argall, Three Rivers.

CHROMIC IRON.

Black Lake Chrome and Asbestos Company, Black Lake.
American Chrome Company, Black Lake.
Star Chrome Company, Colraine.
Canadian Chrome Company, St. Hyacinthe.

COPPER.

Eustis Mining Company, Eustis.
Nichol's Chemical Company, Limited, Capelton.
J. McCaw, Sherbrooke.
A. O. Norton, Coaticook.
G. E. Smith, Sherbrooke.
A. F. Foss, Lennoxville.

GOLD.

Cie des Mines d'or de Pontiac and Abitibi, Limited, Montreal.
C. A. Parsons, South Dudswell.
Louis Mathieu & Cie., Beauceville.
Louis Gendreau, Jersey Mills.
C. E. Kennedy, Beebe Plain.
Marsboro Gold Mining Syndicate, Sherbrooke.

GRAPHITE.

The Bell Mines, Buckingham.
Diamond Graphite Company, Buckingham.
Buckingham Graphite Company, Buckingham.
Calumet Mining and Milling Graphite Company, Calumet.

MANGANESE.

Magdalen Islands Development Company, Montreal.

ASBESTOS.

Bell Asbestos Company, Limited, Thetford Mines.
King Asbestos Mines, Limited, Thetford Mines.
Johnson Asbestos Company, Thetford Mines.
Beaver Asbestos Company, Thetford Mines.
American Asbestos Company, Limited, Black Lake.
Standard Asbestos Company, Limited, Black Lake.
Dominion Asbestos Company, Limited, Black Lake.
Union Asbestos Mine, Black Lake.
Megantic Asbestos Company, Black Lake.
James Reed, Reedsdale.
Broughton Asbestos Fibre Company, Limited, East Broughton.
Quebec Asbestos Company, East Broughton.
Eastern Townships Asbestos Company, East Broughton.
Frontenac Asbestos Mining Company, East Broughton.
Boston Asbestos Mining Company, East Broughton.
Asbestos Mining and Manufacturing Company, Chrysolite.
Asbestos and Asbestic Company, Danville.
R. H. Martin, New York, U.S.
Colraine Asbestos and Exploration Company, Limited, Colraine Station.
Premier Mining Company, Colraine Station.
Beauceville Asbestos Company, Beauceville.
Ottawa Asbestos Mining Company, Ottawa.

MICA.

Blackburn Bros., 46 Sussex St., Ottawa.
Wallingford Mica and Mining Company, 41 Duke St., Ottawa.
Wallingford Bros., Limited, 24 Central Chambers, Ottawa.
Fortin & Gravelle, Hull.
General Electric Company, Isabelle St., Ottawa.
Laurentides Mica Company, corner of Bridge and Queen, Ottawa.
Vavassour Mining Association, E. F. Nellis, 22 Metcalfe St., Ottawa.
Comet Mica Works, 398 Wellington St., Ottawa.
Lila Mining Company, D. L. McLean, 6 Sparks St., Ottawa.
Allan Gold Reefs Company, Limited, Victoria Chambers, Ottawa.
Webster & Co., 274 Stewart St., Ottawa.
Thomas J. Watters, Metropolitan Bldg., Ottawa.
Brown Bros., Cantley.
Lewis MacLaurin, East Templeton.
Richard Moore, Picanock.
Joshua Ellard, Picanock.
Glen Almond Mica and Mining Company, Buckingham.
Kent Bros., Kingston, Ont.
Henry F. Flynn, Maniwaki.
Chabot & Cie., Ottawa.
Gatineau Valley Mica Company, H. H. Moore, Cantley.
C. W. Berry, 424 McLeod St., Ottawa.
Calumet Mica Company, Bryson.
Cawood Mica Company, 38 Sparks St., Ottawa.

WHITE MICA.

Canadian General Mining Company, Limited, P.O. Box 253, Montreal.

PURCHASERS OF MICA.

Laurentides Mica Company, Limited, Bridge and Queen Sts., Ottawa.
Eugene Munsell & Co., 332 Wellington St., Ottawa.
General Electric Company, Isabella St., Ottawa.
Webster & Co., 274 Stewart St., Ottawa.
F. D. Moore, 354 Wellington St., Ottawa.
Ottawa Mica Company, Hull.
A. Roy Macdonald, Jr., 68b St. Urban St., Montreal.

PHOSPHATE.

J. F. Higginson, Buckingham.

FELDSPAR.

W. A. Allan, Victoria Chambers, Ottawa, Ont.

MAGNESITE.

E. J. Waters, 554 Rideau St., Montreal.

KAOLIN.

F. R. Lanigan, 23 Cote St., Montreal.

TALC.

C. V. M. Temple, 175 Spadina Rd., Toronto, Ont.

SULFATE OF BARYTA.

Canada Paint Company, 372 William St., Montreal.

COMBUSTIBLE NATURAL GAS.

Canada Gas and Oil Company, Three Rivers.

PEAT.

Imperial Light, Heat and Power Company, Limited, Liverpool, London and Globe Bldg., Montreal.

SLATE.

Rockland State Quarry, New Rockland.

FLAG STONES.

F. R. Bishop, Bishop's Crossing, Co. Wolfe.

CEMENT.

International Portland Cement Company, Limited, Hull.
The Lakefield Portland Cement Company, Limited, Pointe aux Trembles.
Vulcan Portland Cement Company, Limited, Longue Pointe.

GRANITE.

Stanstead Granite Quarries Company, Limited, Beebe Plain, Co. Stanstead.
S. B. Norton, Beebe Plain.
James Brodie, Graniteville, Co. Stanstead.
The Whitton Granite Quarry Company, St. Victor de Tring.
M. Fitzgerald, Sainte Cecile, Co. Compton.
Fortunat Voyer, Riviere a Pierre, Co. Portneuf.
Joseph Perron, Riviere a Pierre.
M. P. Davis, 48 Central Chambers, Ottawa.
The Laurentian Granite Company, Limited, Montreal.
J. A. Nadeau, Iberville.
Montfort Granite Company, Limited, Montreal.

BRICKS—(The principal companies).

Thomas W. Peel & Co., Montreal.
J. Burnet & Cie., Montreal.
Chs. Sheppard & Son, Montreal.
Joseph Bernier, Montreal.
Joseph Descarrie, Montreal.
Laprairie Brick Company, Limited, Laprairie.
Narcisse Blais, Quebec.
Paradis & Letourneau, Quebec.
Laliberte & Fils, Saint Jean Deschaillons, Co. Lotbiniere.
Victor Charland, Saint Jean Deschaillons.
D. G. Loomis & Son, Sherbrooke.
The Eastern Townships Brick and Manufacturing Company, Lennoxville.

LIME—(The principal companies).

Dominion Lime Company, Sherbrooke.
Cyrille Gervais, Montreal.
Olivier Limoges, Montreal.
Montreal Line Company, Montreal.

BUILDING STONE.

The Terrebonne Quarry Company, St. Francois de Sales, Co. of Laval.
The Louis Labelle Quarry Company, Limited, St. Francois de Sales.
Joliette Limestone Quarry Company, Joliette.
Standard Lime and Quarry Company, Joliette.
Frelighsburg R. and Quarry Company, Philipsburg, Mississiquoi.
Harrisson Quarry Company, Montreal.
Dominion Quarry Company, Montreal.
O. Limoges, Montreal.
Grondine Stone, Lime and Brick Company, Three Rivers.

COMPANIES USING CERTAIN PRODUCTS OF THE MINES TO BE MANUFACTURED IN THIS PROVINCE.

The Electric Reduction Company, Limited, Buckingham, ferrochrome and phosphorus.
The Chemical and Fertilizer Company, Buckingham, superphosphate.
Electro Manganese Reduction Company, Shawenegan.
Standard Chemical Company, Coaticook, acetate of lime.
The Standard Drain Pipe Company, Limited, St. Jean d'Iberville.
C. E. Dubord, Beauport, refractory clay.
Geo. Belanger, Beauport, refractory clay.
The Montreal Terra Cotta Company, Limited, Maisonneuve.

ALBERTA.

MINES OPERATED IN ALBERTA DURING 1907.

Canmore, H. W. McNeill Co., bituminous.
Lethbridge, Alta. Ry. & Irr'n. Co., lignite.
Clover Bar, Daly & Lindsay, lignite.
Clover Bar, Clover Bar Coal Co., lignite.
Namao, C. G. Carnegie, lignite.
Strathcona, Wetaskiwin Coal Co., lignite.
Namao, Frank Smith, lignite.
Strathcona, White Star Coal Co., lignite.
Lineham, Cooper & McPherson, lignite.
Cardiff, Cardiff Coal Co., lignite.
Medicine Hat, Crockford Bros., lignite.
Taber, Reliance Coal Mining Co., lignite.
Hillcrest, Hillcrest Coal and Coke Co., bituminous.
Edmonton, Wm. Humberstone, lignite.
Edmonton, Milner-Benner Coal Co., lignite.
Strathcona, Strathcona Coal Co., lignite.
Frank, Canadian-American Coal and Coke Co., bituminous.
Edmonton, Edmonton Standard Coal Co., lignite.
Carbon, Knee Hill Coal Co., lignite.
Lethbridge, James Ashcroft, lignite.
Lethbridge, Geo. F. Russell, lignite.
Pincher Creek, W. H. Wall, lignite.
Lundbeck, Galbraith Coal Co., lignite.
Medicine Hat, Fred Scott, lignite.
Lille, West Canadian Collieries, bituminous.
Clover Bar, Keith & Fulton, lignite.
High River, Wm. Ellis, lignite.
Gleichen, Blackfoot Indians, lignite.
Edmonton, Milner-Benner Coal Co., lignite.
*Namao, Watson Bros., lignite.
Lundbreck, Alberta Coal and Coke Co., lignite.
Lundbreck, Alberta Fuel Co., lignite.
Bankhead, Bankhead Mines, Limited, anthracite.
Taber, Duggan, Huntrods & Co., lignite.
Bellevue, West Canadian Collieries, bituminous.
Coleman, International Coal and Coke Co., bituminous.
Edmonton, Western Coal Co., lignite.
Clover Bar, Byers Bros., lignite.
Clover Bar, P. Ottewell, lignite.
Lethbridge, Royal Collieries, Limited, lignite.
Clover Bar, Byers Bros., lignite.
Strathcona, Fraser & Freeman, lignite.
Namao, Lindsay Bros., lignite.
*Carstairs, S. Downie & Sons, lignite.
Lethbridge, Diamond Coal Co., Limited, lignite.
Taber, Canada West Coal Co., lignite.
Taber, Domestic Coal Co., lignite.
Edmonton, Parkdale Coal Co., lignite.
Namao, Charles Carnegie, lignite.
Taber, Stevens Bros., lignite.
Three Hills, Three Hills Coal and Development Co., lignite.
Three Hills, Nichols & Bothamley, lignite.
Taber, John Howells, lignite.
Carbon, Dodds, Currie & Hoding, lignite.
Three Hills, Jarvis & Bowden, lignite.
*Three Hills, C. F. Bothamley, lignite.
*Medicine Hat, J. Evans, lignite.

*High River, C. E. McIntosh, lignite.
Nanton, B. Parton, lignite.
*Carbon, Carbon Brick and Coal Co., lignite.
Woodpecker, J. Marsh, lignite.
Edmonton, Ketchum Coal Co., lignite.
Burmis, Leitch Collieries, Limited, bituminous.
*Strathcona, Larry Garneau, Jr., lignite.
Edmonton, Rosedale Coal Co., lignite.
*Morinville, Alberta Coal Mining Co., lignite.
*Taber, Central Coal Co., lignite.
Taber, Fox & Simms, lignite.
Taber, Canadian Pacific Railway, lignite.
*Bellevue, Maple Leaf Coal Co., bituminous.
*Brant, S. Wadsworth, lignite.
Lethbridge, W. Stafford, lignite.
Bowville, Henry Therriault, lignite.
Reidhill, James Ashmore, lignite.
*Taber, International Land Development Co., lignite.
*Woodpecker, Thomas Patterson, lignite.
Woodpecker, John Marsh, lignite.
Namao, Namao Coal Co., lignite.
Three Hills, Geo. Watson, lignite.
Claresholm, W. J. Bell, lignite.
Pincher Creek, Scott & Maclane, lignite.
Pincher Creek, Pincher Creek Coal Mining Co., lignite.
Edmonton, United Collieries, Limited, lignite.
Edmonton, Frank Coal Co., lignite.
Tofield, P. F. Ingram, lignite.
Tofield, Tofield Coal Co., Limited, lignite.
Thigh Hill, S. J. Henry, lignite.
Grassy Lake, H. A. Driggs, lignite.
Burmis, East Crow's Nest Coal Co., bituminous.
Grassy Lake, Grassy Lake Coal Co., lignite.
*Edmonton, Dawson Coal Co., lignite.
Edmonton, Rupert's Land Coal Co., lignite.
Taber, Bucknam & Henderson, lignite.
Taber, Marsh Bros., lignite.
Taber, Imperial Coal Co., lignite.
High River, John Thorne, lignite.
Lethbridge, James Perry, lignite.
Magrath, Magrath Coal Co., lignite.

(*) Indicates "no coal produced."

MINES ABANDONED DURING 1907.

Mine No. 76—Operated by Alberta Coal and Coke Co., Lundbreck. Shaft on N.E. ¼ Sec. 25, Tp. 7, Rge. 2. west 5th Mer. Abandoned in December .1907.
Mine No. 18—Operated by Ramsey & George, Edmonton.
Mine No. 134—Operated by Samuel Wadsworth, Brant, Alto.
Mine No. 138—Operated by International Land Development Co.
Mine No. 57—Operated by W. R. Welsh, Pincher Creek. No. 2 tunnel abandoned December, 1907, by W H. Wall.
Mine No. 139—Operated by Thos. Patterson, Woodpecker.
Mine No. 118—Operated by John Evans, Medicine Hat.

MINES REOPENED DURING 1907.

Mine No. 57—Formerly operated by Wm. McFarlane, Pincher Creek. Sold to Western Oil and Coal Consolidated and leased by them to W. H. Wall. Released December 9, 1907, to Wm. R. Welsh, Pincher Creek.
Mine No. 70—Formerly operated by Riley & Thompson, High River. Reopened 1907 by Wm. Ellis, High River.

FOREIGN SOURCES OF SULPHUR.

Sicily.—For ten years prior to August, 1906, more than three-quarters of the sulphur industry of Sicily had been in the hands of the Sicilian Sulphur Company (Limited), of London, which virtually controlled the sulphur business of the world during that period. When the contract between the English company and the Sicilian sulphur producers came to an end on August 1, 1906, the former had a large stock of sulphur (estimated at 450,000 tons) on hand. To avoid a reduction in the price of sulphur, which would doubtless have involved disastrous results to the industry in Sicily, the Italian Parliament passed a law requiring all Sicilian sulphur to be sold through the "Consorzio Obligatorio," presided over by a royal commissioner, with Government resources behind it. At a conference between representatives of the Sicilian and the American sulphur interests held in July, 1907, the Italians insisted that American sulphur should be kept out of the European market. The American interests declined to entertain such a proposition, and in August, 1907, the situation in Sicily became decidedly threatening as a result of the Italian Government's attempt to reduce wages. About the same time it was decided to throw upon the American market the stock of sulphur accumulated in Sicily. With this end in view a first cargo of 3,000 tons was sent over, and it was understood that more was to follow. In October, 1907, prices on prime Louisiana sulphur to New York, Boston, and Portland were quoted at from $19 to $19.50 per long ton, a drop from $22.25, the price which had obtained during the early part of the year. Early in January of the present year, 1908, the Consorzio and the American producers came to an understanding and prices were again advanced to $22 per ton and have remained at this figure up to the time of writing (June, 1908).

In spite of the fact that quotations have been more than $22 per ton the greater part of the year, it is significant that the exportation of Sicilian sulphur to the United States has shown a constant and marked decline. Four years ago the importation of Sicilian sulphur amounted to more than 100,000 long tons. With the growth of the Louisiana sulphur industry, Sicilian sulphur in the United States has become almost a negligible quantity, as will be seen from the importation from Sicily of but 3,393 long tons in 1907. The following table, reported by Messrs. Emil Fog and Sons, of Messina, of exports of sulphur from Sicily, by countries, during the past four years, indicates the falling off in exports to the United States. This statement shows that 9,476 long tons were shipped from Sicily in 1907, but only 3,393 tons reached the United States during that year. Of the 9,476 tons shipped to this country in 1907, 8,598 tons were best unmixed seconds and 878 tons were refined sulphur.

ABRASIVE MATERIALS IN THE UNITED STATES.

Production in 1907.

The domestic abrasive material industry was in much better condition in 1907 than in any previous year, according to a report by W. C. Phalen, just issued by the United States Geological Survey as an advance chapter from "Mineral Resources of the United States, Calendar Year 1907."

The total value of all the natural abrasives produced during the year—including millstones and buhrstones, grindstones and pulpstones, oil stones and scythe stones, corundum and emery, abrasive quartz and abrasive feldspar, garnet, infusorial earth, tripoli and pumice—was $1,680,737. Compared with the value of the output for 1906—$1,473,393—this is an increase of $207,344. There was also a large increase in the production of artificial abrasives—carborundum, alundum and crushed steel—14,632,000 pounds, valued at $1,027,246, having been produced in 1907, as compared with 11,774,300 pounds, valued at $777,081, in 1906, a gain of $250,165. The total gain in value of abrasives of both classes was therefore nearly half a million dollars; there was, however, a decrease in value of imports of natural abrasives of $155,824, making a net increase in the domestic consumption of abrasives of all kinds for the year of $301,685, as compared with an increase of $376,437 in 1906.

Natural abrasives were produced in 23 States in 1907, as compared with 25 States in 1906.

The following table shows the value of the different kinds of abrasives produced in the United States in 1906 and 1907.

Value of Abrasives Produced in the United States in 1906 and 1907.

	1906.	1907.
Oilstones and scythe stones	$268,070	$264,188
Grindstones and pulpstones	744,894	896,022
Buhrstones and millstones	48,599	31,741
Pumice	16,750	33,818
Infusorial earth and tripoli	72,108	104,406
Abrasive quartz and feldspar	121,671	126,582
Garnet	157,000	211,686
Corundum and emery	44,310	12,294
Artificial abrasives	777,081	1,027,246
	$2,250,474	$2,707,983

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Halifax.

Mr. Franklin Playter, of Boston, who is the treasurer and general manager of the Boston-Richardson Gold Mine, has given out a statement for publication. In the summer of 1907 the company commenced building and equipping large additions to their plant. This involved heavy expenditure and large obligations. The bulk of the ore mined carries not more gold than $3.00 per ton. To work this at a profit the large plant was essential. The financial depression made the company's creditors urgent in their demands. The mine, whilst it is easily able to produce many times the requisite amount of ore to pay off all obligations, cannot do this in a few months. The treasurer advanced $15,000 of his own money, but this was insufficient to tide over the difficulty. Hence the company has been placed in the hands of a receiver.

THE BOSTON-RICHARDSON.

Goldboro.

A correspondent has provided the Canadian Mining Journal with a constructive suggestion as to the manner in which the Government can most profitably assist the Boston-Richardson Mine, which has recently gone into the hands of a receiver.

The mine is in good shape physically. If the management could be relieved temporarily from the burden of accrued liabilities, and could be supplied with, say, $20,000, for current operating expenses, then success is a moral certainty.

As a guarantee for any money advanced there is a reserve of 18,000 tons of ore, broken in the stopes, which will yield a net profit of at least $1.00 per ton.

There is also a live contract for the arsenic contents of the concentrates. This contract, despite the low current prices paid for arsenic, yields a net profit of $2,000 per month. The material accumulated in the tailing pile will supply shipping material for at least two years. This contract has been arranged recently. Fifty tons of arsenic concentrates is the monthly output.

If the Government, after due investigation of the above statements, would guarantee an issue of Receiver's Certificates for the necessary amount, the money could be raised with no difficulty.

The mine, as stated above, is in excellent shape. The plans for enlarged plant have been almost carried out. New machinery is on the ground with which a capacity of 8,000 tons of ore per month will be reached. The mine is well developed for this production. The costs per ton, during the last eight months, were below $1.80 per ton.

Considering all these facts and the additional fact that the closing of the Boston-Richardson will be of incalculable injury to the Province, it is not asking too much of the Government to request that an adequate sum of money be appropriated as promptly as possible.

The Government need have no fear of buying a pig in a poke. The amplest investigation will be welcomed.

Glace Bay—August 19.

Things have been rather slack around the collieries during the month of August. The usual succession of picnics and holidays have demoralised the routine and very considerably reduced outputs, which will be much lower than they have been throughout the preceding months of this year.

As announced some time ago, Mr. Charles Fergie has resigned the position of Superintendent of Mines for the Dominion Coal Co., and, following on this, several changes and promotions have taken effect in the official staff. Mr. Richard Kirby, late of England has been appointed Mining Engineer to the Coal Company. The whole of the mines are now separated into three districts, each of which will be in charge of a Divisional or District Superintendent, reporting directly to the General Manager. Mr. Alexander McEachern, the late Manager of Reserve Mines, is promoted to be District Superintendent of No. 1 District, comprising Mines Nos. 1, 5, 10 and 8. No. 2 District, comprising Mines Nos. 2, 9 and 7 remains as before under the superintendence of Mr. Norman MacKenzie. Mr. Peter Christianson is District Superintendent of District No. 3, which comprises Nos. 6, 3, 4, 12 and 14.

The North Atlantic Collieries Co. have decided to sink a shaft to the Blockhouse Seam at Port Morien, which they have just proved by a borehole. Our metropolitan newspapers gave prominence to the fact that the Blockhouse Seam had been "found." We did not know that it had ever been lost. Surely in its old age the Blockhouse is not going to play hide and seek like the giddy "Mullins" seam.

The Town of Glace Bay has acted with commendable promptitude in answer to the appeal of the Mayor of Fernie for funds to relieve the distress caused by the recent forest fires. The Mayor called a public meeting, and it was decided to send $1,000 and collect the money afterwards, and this was done. The impulsive generosity of mining populations is proverbial. They realize that some day they themselves may have to ask outside assistance. The city of Sydney is still considering "ways and means," and many of its citizens feel that their city has been outdone by its neighbor, and feel ashamed.

In a recent conversation with a Sydney newspaperman the president of the Dominion Coal Company recalled the fact that when he first took charge of the Coal Company the output of that corporation was in the neighborhood of 2,000,000 tons per annum, and that during the seven years which have since elapsed this output has been raised to 4,000,000, or figures in that neighborhood. Mr. Ross went on to say that within the next septennial period he anticipated an equally great advance in outputs. This would mean that in 1915 the output of the Coal Company's mines may be around 8,000,000 tons, or equivalent to the present total annual production of Canada. Coming from such a man of deeds as the president of the Dominion Coal Company this is a very pregnant prediction, and its true significance requires a little study to become fully apparent. An increase in outputs of 4,000,000 tons in seven years would mean a capital outlay of between ten and fifteen million dollars in the development and equipment of new mines, the provision of rail facilities and rolling stock, of new coal freighting steamers and loading and discharging plants. It would mean the doubling of the present mining population with all the attendant growth that comes with increase of population. It means the opening up of new avenues of work, and wealth and promotion for the people of the "Far East" of Canada.

Although over 300 years have elapsed since the pioneers of civilization came to Cape Breton, this island is only jut coming into its own, for there never was anything phenomenal about Cape Breton. Somehow progress in the East seems to be slower than in the West, but such growth as we have is solid as it is slow. Although in the rush for the wealth of the West, this corner of the Dominion has been overlooked, yet we have our compensations. Our climate is equable, we are out of the hurricane belt, cataclysms and earthquakes never trouble us; floods and fires and blizzards and other vagaries of Nature, such as vex the untamed West, come but once in centuries to this island, and although Cape Breton is not exactly the land of the Morning Calm, yet we have some advantages and compensations that make up for a less spectacular wealth and a growth that is slower than that of the West.

It is rather a coincidence, in the light of to-day, that Sydney might have been named Pittsburg. This was the name chosen for it by Governor DesBarres when Sydney was laid out by British soldiers in the days of the Georges. Some day it may rival in importance its Pennsylvania cousin, who can tell.

Stirred to definite action by the dreadful loss of life which marked the year 1907 in the mining annals of the United States, the Government of that country has appropriated the sum of $150,000 to establish experimental galleries and rescue stations in the coal regions of Pennsylvania and Virginia, and has called a convention of mining experts from Europe to meet in Pittsburg on September 1st.

The "Montreal Gazette" in commenting editorially on this action of the authorities in the States says: "The experimental work which is to be inaugurated at Pittsburg, dealing as it will with conditions similar to those to be found here, should therefore prove of decided value to the Canadian miner of the future. The courtesies of the United States Bureau of Public Documents seems to know no international boundaries, and we have no doubt that the monthly bulletins of progress that are promised by the new Bureau of Safety will be welcomed in Canada as additions to existing Canadian literature on this general subject." But the "Gazette's" comment is open to misapprehension. Are Canadian mining conditions similar to those in the United States? Does the "Gazette" know that the rate of fatalities in the mines of the United States is the highest in the world, and that the same rate in the mines of Nova Scotia is the lowest? We do not think that the public press of Upper Canada realizes the status of Canadian coal mining. To a Canadian mining company belongs the honor of having had the courage and the humanity to erect the first completely equipped "Rescue Station" on this continent. The Dominion Coal Company have had such a station for a year, and they have at the present time 39 complete sets of Draeger apparatus, housed in a brick building, with all the accessories of a modern rescue station, They have also a practice building, in which men are trained to wear the apparatus and work with it under conditions closely approximating to those underground, and in entirely unbreathable atmospheres. They employ a paid instructor specially engaged in England, and the work of training men is continuously going on, necessitating constant expenditure on oxygen and other supplies.

We think also it is fair to point out that the pioneer of experimental work of the nature to be undertaken by the United States Bureau is an Englishman, Mr. W. E. Garforth, of the Normanton Collieries, Yorkshire. Mr. Garforth for many years, entirely at his own expense, has carried on experiments of a costly and extensive nature to determine the explosive properties of coal dust, the effect of detonation and mine blasts on the flame of safety lamps, and he is the inventor of an approved type of oxygen breathing apparatus. Recently the British Home Office granted Mr. Garforth a subsidy to aid him in his valuable work, and the most accurate and up-to-date information on the subject is to be found in the British Blue Books and the Transactions of the English Institution of Mining Engineers. It may be of interest to remark that the original prototype of oxygen regenerative breathing apparatus intended to facilitate rescue work in mines was invented twenty-seven years ago by Mr. Henry Fleuss, of Newcastle-on-Tyne, and this apparatus, very little modified, is manufactured at the present time by Siebe-Gorman of London.

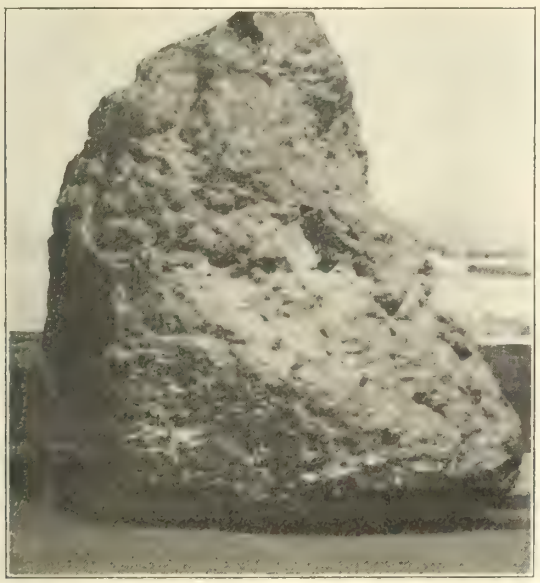
As has been previously pointed out in the columns of the Canadian Mining Journal, the provision of property equipped rescue stations and the training of men to act as special rescuers is one that is national in its character. This fact has evidently been recognized in the States, and it must eventually be recognized here. In the meantime, as was the case in England, no doubt the pace will be made by individual and corporate effort. Although Canadian miners will heartily welcome any information that can be given them by their confreres in the United States, we think they will have to work out their own salvation, and we further think they are doing it remarkably well. One of the gentlemen who is soon coming to visit us with the English delegates from the Institution of Mining Engineers has recently been telling his colleagues through the columns of the "Colliery Guardian" that Canadian miners were being taught to "hustle" by their rivals in the States. We venture to assert that the average Canadian miner needs no lessons in "hustling," as this gentleman will find when he reaches Glace Bay.

Judge Russell, of the Supreme Court of Nova Scotia, has recently given a judgment which is of more than ordinary interest to the owners of coal areas in the Province. The suit in question was a very bare-faced attempt to deprive the Dominion Coal Company of their ancient title to the Point Aconi submarine coal leases near Sydney Harbour. The general manager of the coal company, in a communication to the "Montreal Star," stated that suit was inspired by the Dominion Iron and Steel Company, and was regarded by the coal company as "an unblushing act of piracy on the part of the steel company." The original leases were granted by the Mines Office in 1866, and have been renewed at intervals of twenty years since. The claim of Mr. Burchell, who acted for the steel company in this matter, was based upon alleged inaccuracies in the official plan and upon technicalities so trifling as to be practically unexplainable. The main leases of the Dominion Coal Company were secured to them by Act of Parliament at the time of incorporation for a period of ninety-nine years, but outside this blanket lease all other Nova Scotian coal leases are based upon the plans of the Mines Office, which the steel company endeavored to prove incorrect. Had the contentions of the coal company's opponents been upheld it would have put all other coal owners in a position of embarrassment and incertitude as to the validity of their titles. From olden times men have invariably respected ancient landmarks, and have regarded the remover of such as the common enemy. Although the judgment given in this case will give claim jumpers pause, yet it is very disconcerting to find that original grants from the Crown of such ancient standing can be so easily and wantonly attacked.

One of the Montreal newspapers in referring to the Elk River fire, which it was said at one time might involve the coal mines of the Crow's Nest, quoted some one in the Geological Department at Ottawa as having said that the outcroppings of the coal seams along the Cape Breton shore had been deliberately set on fire by the French before they evacuated the country at the time of the British occupation. This is certainly a very long time ago, yet we should be glad to learn where the geological gentleman in question obtained his information. No one in Cape Breton seems to have heard this version before, and it is not referred to in that vade mecum of early days of coal mining here, Mr. Richard Brown's history. It is very generally understood these outcrop fires were started by coal smugglers in the days when it was an offence to mine coal in Cape Breton. In this year of the Tercentenary, and the culmination of the entente cordiale in the Franco-British Exhibition, it is only right to call in question such an aspersion on the memory of the gallant gentlemen who sleep at Louisburg, and who fought their last for the fair lilies of France.

ONTARIO.

Cobalt.



Crown Reserve. Returns from a car of 23 tons, consisting of 100 bags of screenings and 150 bags of No. 1 ore, the shipment averaged 5,300 ounces of silver or nearly $3,100 for the car. Approximately 85 per cent. of the values were in the 150 bags of high grade ore.

Trinity Cobalt.—The new plant on the Trinity Cobalt is in operation. The shaft, which is being sunk to 100 feet is now down 35 feet.

Viceroy Cobalt.—Work will be started at once on the property of this company, located in Lot 8, Concession 4, Coleman. The control of this company has passed to a syndicate of Ohio oil men.

Red Rock.—On Friday, July 24th, work was stopped here. Supt. W. R. Thompson has left the camp. It is understood that the suspension of work was due to lack of funds.

Nipissing.—The surface prospecting which has been carried on by this company on their property within the limits of the town of Cobalt, has given the town the appearance of a mining town in the fullest sense of the word. Twenty-five men have been employed trenching across vacant lots, between houses and along the streets for two weeks. In one case a trench was dug for several hundred feet with no result. Argentite street was reached, the street was skipped to be prospected at some later date and the trench continued for some distance. During the noon hour the foreman of the trenching gang, while

NUGGET FROM GROVER ADLEN SMITH.
Property in S. Lorrain. Weight 117½ lbs.

waiting for his men, noticed some cobalt bloom on an outcrop by the roadside and with his pick uncovered an 8 to 10 vein of smaltite and silver, which assayed 10,000 ounces. This vein is numbered 100 on the map of the Nipissing. A few days later vein 101, a narrow but very rich vein of calcite and silver was found in a cross trench 200 feet distant. Four shafts are being sunk within the town limits, one of which, known as the Promise shaft, is expected to locate the extension of the La Rose Right of Way vein.

The quarterly statement of the Nipissing Mining Company compares with the last statement as follows:

	July 1, '08	April 1, '08
Cash in bank and bullion on hand.	$705,400	$614,974
Ore in transit and at smelters....	169,096	158,491
Ore sacked.	112,235	200,030
	$986,731	$972,495

Approximately 13,000 shareholders received checks for the quarterly dividend.

Progress.—Operations will be resumed at once on the Progress property, situated south of the Temiskaming. A new boiler and hoist will replace the ones destroyed in the recent fire and a new three-drill compressor will be installed.

There are now eleven mines on the list of regular dividend payers, the Buffalo City, City of Cobalt, Coniagas, Crown Reserve, Kerr Lake, McKinley-Darragh, Nipissing, Right of Way, Silver Queen, Temiskaming and T. & H. B. The Trethewey and the La Rose Consolidated will undoubtedly be added to the list in the near future.

In the first six months of 1908 these mines paid a total of $1,504,591, making the total dividends paid by Cobalt companies to July 31, 1908, $5,551,701. This does not include the O'Brien, Drummond and La Rose mines which are close corporations. These properties have paid approximately $2,500,000 in profits to their owners.

Maple Mount District.

Montreal River.—Supt. R. W. Foster, of the Canadian Ores, Limited, states that he has sacked 130 bags of high grade ore from the 30-foot shaft on the main vein. The work this summer has been principally confined to prospecting. Twenty-four veins have been located, five of which have been trenched. A new cobalt vein six inches wide, was found last week. Mr. Foster expects to sink the No. 1 shaft 200 feet and develop all of the veins from this shaft. He is at present operating one drill, a small boiler and hoist. A seven drill compressor, new boiler and 10 x 12 hoist have been purchased and will be installed this winter. Silver has recently been found on both the Enright and Gillies properties in this section.

Miller Lake.—The reports of important discoveries in the vicinity of Miller Lake, a small body of water lying five miles southwest of Bloom Lake, have been confirmed. There is every indication that this area will prove to be richer than the Silver Lake section. The most valuable discovery so far made is on the Gates claims, orginally staked last May by Cartwright and Le Heup. The vein, which is three to four inches wide, is smaltite and silver and has been traced 240 feet. Several good discoveries have also been made on the Bonsall claims.

BRITISH COLUMBIA.

Rossland.

The three leading mines of this camp, the Centre Star group, the Le Roi and the Le Roi 2, Limited, are making an exceptionally good showing when it is considered that the market price of silver and copper is at such a low figure. While the gold is the chief value found in Rossland ore, the fluctations in the price of copper and silver affects the profits of the mines to quite an extent. It is said that the Centre Star group is earning a net profit of $35,000 to $38,000 per month; the Le Roi falls considerably under this but are yet putting money aside each month and, to be brief, the Le Roi 2, Limited, continues to pay a two shilling dividend every few months.

The lessees of the Blue Bird and those who have been operating the Evening Star have made a nice sum of money of their enterprise, but the men who have had several of the other small properties hereabouts under lease have earned very little over expenses. Nothing undaunted, however, a number of the miners are looking about for new showings to delve in, their bosoms full of the hope that possesses nearly every prospector.

At the Centre Star they are shipping second class ore from the dump. This ore was placed on the dump seven or eight years ago when the smelting charges prohibited its shipment to a reduction works, but it is thought that a margin of profit can be made on it under present treatment and freight rates.

The ore shipments from the local mines are averaging from 5,200 to 5,800 tons per week from the large mines with an occasional car of hand picked ore from the small mines. The lessees of the Evening Star are shipping about a car per week and have installed a small steam plant to facilitate the work of getting out ore. The lessees of the Homestake and Sunset have each shipped a car of good ore in the last week.

Boundary.

The shipments from the Boundary's leading shipper, the Granby, have not been as heavy during the last two weeks as they could have been, as they have had several furnaces cold at the smelter connecting them up to the newly installed blowing engines. During the week ended August 15th, for instance, they only shipped 16,039 tons. This, however, was partly owing to the wave of uncertainty that passed over the Boundary district with the news that a devastating forest fire had disabled the coke making apparatus of the Fernie mines. It was feared for a time that the local supply of coke would be used up and the Fernie supply unavailable for many weeks to come, but at this writing no serious delay is apprehended.

The B. C. Copper Company have been shipping from 14,000 to 14,500 tons of ore per week and expected to augment these soon, but they will no doubt delay the increasing of their output until the coke situation is more settled.

The Dominion Copper Company has been shipping over 3,000 tons of ore per week, but as this company did not have a very large store of coke on hand they closed down both mines and smelter in consequence of the Fernie fire. They have now arranged to get a supply of coke from the Pacific Coast if the Fernie mines cannot supply them and will resume work in a few days. The machine shop of the Dominion Copper Company, situated at Boundary Falls, was burned last week. This will cause the company considerable inconvenience. The shop was an up-to-date one. Up to Wednesday, August 12th, for that week the Dominion Copper Company treated 2,204 tons of ore from their Brooklyn, Rawhide, Sunset and Mountain Rose mines.

The Boundary mines are beginning to realize the result of their efforts to keep the cost of ore and copper production down to as low a point as possible. The Granby Company is making copper for a fraction over eight cents per pound, and the B. C. Copper Company have got their costs down so that they can land copper in New York for about 9¾ per pound, and they intend to lower this figure when they increase their output.

Work on a number of the smaller properties is progressing favorably. Good results are being obtained on the Diamond-Texas, E. P. U., Tip Top and other growing properties around here and operations will shortly be resumed on the Skylark, Prince Henry and two or three other prospects. A tunnel is being driven on the Golden Eagle. It is expected that sufficient ore will be taken out during the course of the work to pay expenses.

The Humming Bird has been bonded to New York capitalists. An average shipment of 468 tons of ore from this property recently returned $26.66 per ton.

W. Y. Williams, consulting engineer for the Granby Company, has just returned from a trip to the Similkameen district, where, among other things, he looked over the work now being done on the copper property at Bear Creek. A large body of good ore has been blocked out at this mine and shipments will be made as soon as the railway, now rapidly approaching that point, is in a position to handle ore.

The party of the Geological Survey of Canada are reported as making good progress with the survey at that point. This is valuable work from the standpoint of the mining men and the Government will be amply repaid for the work by the mining industry in years yet to come.

A force of twelve men is working at the Golden Zone, near Hedley, and the 10-stamp mill, with 5-stamp equipment at present, is working satisfactorily. Ore is being taken from a glory hole and dropped into the bins connected with the mill which are close to the work.

The fortunes of McKinley Camp fluctuates probably more than any section in this country. One day we hear of a strike of rich ore and the bonding of a group of claims by outside capitalists and later on the bond has been thrown up and things look dull again. This is largely due to lack of railway facilities and there is little doubt but that when the railway now being built reaches that camp it will make a name for itself. Assays from a 3-foot paystreak on the Victor at McKinley give $80 in gold per ton, while samples taken from the C. P. R. claim have shown as high as 18 ounces gold to the ton.

Nelson.

The Kootenay Development Company has leased the Silver King mine and will operate the mining machinery hereafter with electric power.

The Van-Roi Mining Company of London will hereafter control the destinies of the Vancouver group, which the Le Roi 2, Limited, have been developing. The capital of the new company is £34,500.

The shipments of ore from this section averages 1,650 tons per week at present. This ore is mostly high-grade silver-lead or high grade gold bearing ore.

In the Reco, at Sandon, they have cut a two-foot ledge of good galena ore. Sixty men are now employed in the four stopes being worked at the Silver Cup. A strike has been made on the Nugget, Sheep Creek district, where a narrow shoot has been encountered giving high values in gold.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney, August 13.—About ten days after commencing to sink a bore hole on the north shore of Cow Bay, near the old Blockhouse shipping pier, the North Atlantic Collieries Company has struck the Blockhouse seam at a depth of 120 feet. The seam is reported to be nine feet nine inches thick. The coal is clean and rich and will make a first-class metallurgical coke. The Dominion Coal Company owns part of the territory in which the seam lies.

Halifax.—The cornerstone of the new Nova Scotia Technical College was laid by Lieutenant-Governor Fraser on August 20. Prof. F. H. Sexton, Director of Technical Education, presided, and a number of distinguished citizens spoke.

ONTARIO.

Cobalt.—The management of the Silver Leaf mine has commenced diamond drilling on the north side of the property

Cobalt.—The Temiskaming and Northern Ontario Railway Commission is advertising for tenders for certain mining leases of parcels of mining lands in and near the townsite of Cobalt. Tenders must be received before twelve o'clock noon on September 16th. The leases are for a term of 999 years. The first parcel comprises 13 acres around Cobalt Station; the second contains 4.04 acres of the townsite in the westerly portion of Lot 44; the third embraces Lots 338, 388 and 389 of the townsite, including the mining rights under one-half the streets adjoining said lots. A rental of $1 per annum plus 25 per cent. of the gross value at the mouth of the mine of all ores mined will be reserved for Commission.

Parry Sound.—The discovery of a rich vein of bornite at the McGowan mine, about two miles east of this town, has led to a renewal of agitation for a local smelter. The Canadian Mining Journal will soon publish particulars of the discovery.

BRITISH COLUMBIA.

Fernie, August 12.—A wave of cool weather, followed by a fall of rain has improved conditions here to a remarkable extent. Refugees are returning by carloads from Cranbrook and adjoining towns. It is now possible to purchase meals, and the distribution of free food will be gradually reduced. Phenomenal progress is being made in building. Already several respectable business streets have sprung from the ashes of the obliterated town. The people of Cranbrook have earned the warmest gratitude of Fernie citizens. Their generosity has been boundless.

The Relief Committee has now $80,000 in hand. Provisions and supplies arrive by every train. Premier McBride is expected here in a few days.

Phoenix.—During the first seven months of 1908 the ore shipments of the Granby Consolidated amounted to 619,316 tons, nearly double the tonnage recorded for a similar period in 1907. The monthly returns for 1908 have been as follows:

	Tons.
January. . .	74,203
February. . .	80,155
March. . .	110,2223
April. . .	87,202
May. . .	93,316
June. . .	85,257
July. . .	88,960
Total. . .	619,316

For the same period in 1907 they stood thus:

	Tons.
January. . .	34,192
February. . .	32,465
March. . .	63,826
April. . .	70,158
May. . .	5,072
June. . .	72,820
July. . .	80,216
Total. . .	358,749

Greenwood, August 17.—What might have been a most disastrous fire occurred in the machine shop of the Dominion Copper Company's smelter at Boundary Falls. As it was, the fire entirely destroyed the machine shop and blacksmith shop, entailing a loss estimated by Manager Roosa at from $25,000 to $30,000. Only the hearty, well directed work of the men employed at the smelter and the company's excellent water supply saved the smelter and offices from going.

The building destroyed was a frame structure about 100 x 30 feet and was situated between the trestle and a temporary machine shop and quite near the blower room. The shop was equipped with a lathe 25 inches by 20 feet, a smaller lathe 16 inches by 10 feet, a Cincinnati radial drill, a threading machine, a planer, a shaper, and electric motor and a full equipment of tools and was considered to be, it is said, the best in the Boundary. The building was insured in one of the Ceperly-Rounsfell & Co. companies, but Mr. Roosa did not care to make any statement of the insurance, beyond that all their plant was sufficiently insured.

Nelson.—During the past two weeks of August in the district of which Nelson is the centre, there were 39 mining locations recorded. Eighteen of these were situated in the Sheep Creek and Salmon River districts, and 11 on the other side of the divide near or in the Bayonne country.

Vancouver.—The Guggenheim syndicate secured, on August 12th, an interim injunction against H. B. Hobson working the Cariboo mines. Hobson has a $20,000 clean-up in sight.

Ladysmith.—A new coal mine is being opened by the Wellington Colliery Company, about three miles below Extension near the McLean ranch. The seam lies almost flat and is seven feet wide.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

Coal has been discovered in Devon in the course of quarrying operations near Holsworking. It is not of good quality, but boring will be undertaken to ascertain whether it improves with depth.

The Scottish Coal Trades Conciliation Board have agreed upon a reduction of miners' wages by 12½ per cent.

In the Fife, Scotland, mining area, various extensions are in progress which will give employment to a large number of men.

About 70 coal miners were killed by an explosion which occurred in the Maypole coal mine at Wigan, England, on the 20th inst.

RUSSIA.

Gold discoveries continue to be made in the further East. A rich gold sand area has been discovered on the Tchukot peninsula on the shore of the Sviataya Chresta. The metal has been found at two points 250 versts apart, and the geological formation indicates that it is likely to be found at other places.

The gold and platinum mines on the rivers Tura, Issa, Aklaya and Barautchi in the Ural district, have been flooded and all work stopped. This industry has sustained a heavy loss.

GERMANY.

The existence of extensive lignite deposits near Merseburg has been ascertained by boring and a thick seam has been found in the bed of the River Elster.

The Gewerkschaft Konig Ludwig will construct 60 coke ovens with by-product recovery plant at Recklinghausen.

Thirteen men were killed and eight badly injured as the result of a firedamp explosion in the Dutweiller mine near Saarbrucken on August 11th.

ITALY.

The Sicilian sulphur industry is suffering from over-production. At two of the ports, Empedode and Licata, there is no room for new warehouses and the stocks held are enormous.

CONGO.

Two shipments of gold of the value of $300,000 have passed through Uganda from King Leopold's Kilo mines in the Congo State. It is estimated that over 100 miles in Ituri province will yield gold ore, both allurial and quartz. Foreigners are rigorously excluded.

UNITED STATES.

Eighty per cent. of the coal mines along the Monongahela river are idle and thousands of men out of work, owing to low water in the Ohio river, which prevents shipments being made.

The Amalgamated Copper Company of Butte, Montana, produced in July 20,000,000 pounds of copper from the Washoe smelter, making a new record, at the lowest cost of production per pound in the history of the plant. The cost is gradually being lowered by the introduction of new economies and the treatment of larger amounts of ore.

Work has been resumed on the properties of the Ohio Copper Company at Bingham, Utah. The concentrating mill will be equipped to treat 2,000 tons of ore per day, and when completed will represent an investment of $1,250,000.

AUSTRALIA.

Labor conditions in the coal mining industry of New South Wales and numerous strikes are reported.

The State of New South Wales offers a reward of £500 to the person or company who shall first produce 50,000 pounds of quicksilver from cinnibar ores raised in the State.

Operations in several of the Wolfram mines in the Emmaville district, N.S.W., have been suspended for six months owing to the low price of the product.

SOUTH AFRICA.

The total output of gold in the Transvaal for the first six months of 1908 amounted in value to £14,442,000, of which £13,875,000 was produced by the mines of the Witwatersrand.

MEXICO.

Mr. William C. Seddon and other capitalists of Baltimore have obtained control of 1,500,000 acres of mining property tapped by the Cananea, Yaqui River and Pacific Railroad, and also of the Douglas Copper Company at Fundicion, Sonora, embracing a copper and gold smelting plant.

On July 27th two more furnaces were blown in by the Cananea Cons. Copper Company at Cananea, making a total of four in operation or half the capacity of the smelter. When the whole plant is running the output is expected to average 1,000,000 pounds per month for each furnace.

STATISTICS AND RETURNS.

Shipments from the collieries of the Cumberland Railway and Coal Company, Springhill, N.S., for the month of July were 24,590 tons.

DOMINION COAL OUTPUT TO AUGUST 15TH, 1908.

	Tons.
1	22,400
2	29,170
3	11,860

8	10,060
9	15,160
10	7,410
	152,750

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:

	Week end Aug. 15. Ore in lbs.	Since Jan. 1. Ore in lbs.
*Coniagas	63,780	778,260
*Cobalt Central	46,170	293,685
City of Cobalt		
Drummond	185,480	613,900
La Rose	339,170	4,1[illegible],612
McKinley	125,780	2,145,040
Nipissing	174,860	2,65[illegible],550
O'Brien	128,250	4,054,447
Silver Queen	164,680	1,[illegible]43,990
Temiskaming & H. B.	194,500	918,500

*Concentrates.

The total shipments for the week were 1,422,170 pounds, or 711 tons.

The output of the Crow's Nest Coal Company's collieries for the week ending August 14th was 20,819 tons, a daily average of 3,470 tons.

The output of the Crow's Nest Coal Company's collieries for the week ending August 21st was 16,327 tons, a daily average of 2,721 tons; week ending August 23, 1907, 19,199; a daily average of 3,200 tons; week ending August 24, 1906, 17,122 tons.

COBALT ORE SHIPMENTS.

The total shipments for the week were 1,007,330 pounds, or 533 tons. The total shipments from January 1st to date are 25,832,948 pounds or 12,916 tons.

*Concentrates.

BRITISH COLUMBIA ORE SHIPMENTS.

The shipments for the week ending August 8th have been slightly under the amount shipped weekly recently, although they are in excess of the average for the year. This has been due to the fear of a possible shortage in coke and also to changes still going on at the Granby smelter. However, the trouble is already over and during this week, it is authoritatively stated shipments of coke will have their normal proportions.

It may be noted that the Hewitt mine is now shipping concentrates and the Nugget is getting ready to mill at the earliest available opportunity and for this purpose is building a mill and putting up a short tramway.

The shipments from the various mines and receipts at the smelters for the past week and year to date were:

BOUNDARY SHIPMENTS.

Mine.	Week.	Year.
Granby.	16,000	640,506
Mother Lode.	10,406	89,034
Oro Denoro.	3,970	29,388

Westmount.	86,758	6,770
	9,480,798	4,422,732

The production of the principal copper-producing countries of the world in 1907 was as given in the accompanying table, in metric tons, the figures for 1905 and 1906 being added for comparison:

	1905.	1906.	1907.
Australasia.	34,483	36,830	41,910
Canada.	21,588	19,106	21,022
Chile.	29,632	26,157	27,112
Germany.	22,492	20,665	20,818
Japan.	36,485	40,528	49,718
Mexico.	70,010	62,690	61,127
Peru.	8,763	8,641	10,744
Russia.	8,839	10,658	15,240
Spain-Portugal.	45,527	50,700	50,471
United States.	397,003	416,226	398,763
Others.	397,003	416,226	398,763
Total.	699,514	715,535	723,807

It appears from the above table that the proportion of the total contributed by North America (exclusive of Newfoundland) was 66.44 per cent. in 1907, against 69.60 per cent. in 1906, and 69.85 per cent. in 1905.—Bradstreet's.

COMPANY NOTES.

In a statement of Cobalt dividends printed in our last issue Coniagas Mines, Limited, was not credited with the regular bi-monthly dividend, paid on July 1, 1908, and amounting to $80,000. This omission will scarcely neutralize the pleasure of the stockholders.

The Right of Way Mining Company has declared a dividend of 7 per cent.

MARKET REPORTS.

Coke.

August 21.—Connellsville coke, f.o.b. ovens—
Furnace coke, prompt.
Foundry coke, prompt.

Metals.

Tin, Straits, 29.35 cents.
Copper, prime Lake, 13.70 cents.
Lake arsenical brands, 13.70 cents.
Electrolytic copper, 13.50 to 13.55 cents.
Sheet copper, 18 cents.
Copper wire, 15.25 cents.
Lead, 4.575 cents.
Spelter, 4.70 cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.20 cents.
Aluminium, 32 cents.
Nickel, 45 to 47 cents.
Platinum, $23.50 per ounce.
Bismuth, $1.75 per pound.
Quicksilver, $42.50 per 75-pound flask.

COPPER DISTRIBUTION

Though copper is of world-wide distribution and the United States alone has over 3,000 copper mining companies, W. H. Weed, the American geologist, points out that the world's supply is practically derived from less than 250 mines. This includes only localities supplying 100,000 pounds or more annually. Of such mines the United States contains 58; Japan, 38; Chile, 31, and Australia, 28; but three of these countries produce only 30,000 tons each. Mexico ranks next to the United States in production, while Spain ranks third. Five great mines yield three-fifths of the total production, and one mine alone contributes one-fifth.

Amatite ROOFING

THIS advertisement will bring to your attention the *best and cheapest ready roofing* on the market. Here is how we prove it the best.

In the first place Amatite is made in one standard thickness, whereas other ready roofings range from a thin, flimsy half-ply to a three-ply thickness.

The three-ply thickness (which by the way is only one sheet of felt) is the only kind that can be compared with Amatite.

But right here is the point. Amatite is better made, has better waterproofing material, and weighs more per square foot than the three-ply grade of other makes, and *costs much less.*

These facts make Amatite the most desirable roofing made.

But in addition to its superiority in material and manufacture, Amatite has one distinction which makes it stand out above all others. *It has a real mineral surface.*

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather, the great durability.

This mineral surface is embedded in a layer of Pitch, *the greatest known waterproofing material.* Beneath this in turn are two layers of the best grade of wool felt—cemented together by more Pitch, making the whole a roofing that is *absolutely waterproof.*

No other ready roofing can compare with this mineral-surfaced, water-proof, weather-proof, durable roof. That's why we say—*Don't buy your roofing until you have seen Amatite.*

Free Sample and Booklet

Send for Free Booklet and Sample today. It will pay you to get acquainted with Amatite. Address nearest office.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Temiskaming and Northern Ontario Railway Commission

TENDERS FOR MINING LEASE

Sealed tenders addressed to the undersigned and endorsed "Tender for Mining Lease," will be received at the office of the commission, 25 Toronto Street, Toronto, up to 12 o'clock noon on Wednesday, the 16th day of September, 1908, for mining leases for 999 years of the following parcels:

PARCEL 1.—The Cobalt station grounds, comprising 13 acres, more or less, the right of way adjoining the station grounds to the south, containing 1.15 acres, more or less, and the right of way to the north of the station grounds, and comprising 2.68 acres, more or less, all as shown on plan which may be inspected at the office of the Commission, Toronto, and the office of the Mining Engineer, Cobalt.

PARCEL 2.—The westerly portion of lot 44, in the Townsite of Cobalt, containing 4.04 acres, more or less, as shown by another plan which may be inspected at the office of the Commission, Toronto, and the office of the Mining Engineer, Cobalt.

PARCEL 3.—Lots 338, 388 and 389, in the Townsite of Cobalt, including the mining rights under one half the streets adjoining said lots.

An accepted cheque upon a chartered bank of Canada, payable to the order of the Chairman and Secretary-Treasurer of the Commission, for the amount of the cash bonus tendered for such lease, must accompany each tender.

Forms of tender and of proposed leases (reserving a rental of $1 per annum, plus 25 per cent of the gross value at the mouth of the mine of all ores mined), and full information and plans showing location of each parcel may be examined at the office of the Commission in Toronto, and the office of the Mining Engineer, Cobalt.

All tenders must be made on the form supplied by the Commission for the purpose and signed with the actual signatures of the parties tendering.

In case of each parcel, the party whose tender is accepted will be required to promptly execute a lease in form satisfactory to the Commission, failing which his deposit will be absolutely forfeited to the Commission.

The cheques sent in by unsuccessful tenderers will be returned to them.

The Commission does not bind itself to accept the highest or any tender.

A. J. McGEE, Secretary-Treasurer.

Toronto, Aug. 6, 1908.

Papers inserting this advertisement without authority will not be paid for it.

The National Portable Drilling Rig

THE RIG THAT DISPLACED THE OLD STANDARD DERRICK

The best rig on the market for drilling Oil, Gas, Water, Salt or Mineral Test Wells.

Made in two sizes: Regular pattern for drilling not more than 1,600 feet; Heavy pattern for drilling to a depth of 2,500 feet.

Here is a rig that is built like a machine. ALL THE WHEELS, ETC., ARE MOUNTED ON A STEEL FRAME.

CLYDE PATENT WIRE ROPE WORKS

Rutherglen, Glasgow, Scotland

WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. SPECIALLY FLEXIBLE ROPES for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. SPECIAL ROPE FOR LOGGING.

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of their haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz :

Nova Scotia : Wm. Stairs, Son & Morrow, Limited. New Brunswick : W. H. Thorne & Co., Limited.
Montreal and Toronto : Drummond, McCall & Co. Vancouver, B.C. : John Burns. Winnipeg : David Philip, Portage Ave.

HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.

Cables : "Ropery, Rutherglen." Codes : A. B. C. (4th and 5th Editions), A.I., Liebers and Private.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre :

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions : The full price must be paid in cash ; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to :

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

JUDICIAL SALE

of all Assets of the Copper Mining and Smelting Company of Ontario, Limited in Liquidation.

Sealed tenders will be received, addressed to His Honor F. W. Johnson, Local Master, Sault Ste. Marie, Ontario, and marked "Tenders in THE COPPER MINING AND SMELTING COMPANY of Ontario, Limited, Liquidation," up to twelve o'clock noon on the Fifteenth day of September, 1908, for the purchase of all the assets of the said Company now in the possession and control of the Liquidators, which assets consist of the valuable Mine and Mining Property situated in the Town of Bruce Mines in the District of Algoma and Province of Ontario, on the North shore of Lake Huron (where there is a good harbour and shipping facilities) with machinery, buildings, plant and full equipment situated on the premises, and wharfage, railway tracks and sidings.

Tenders will be received for the entire property or for any of the following parcels :

PARCEL 1

Mine, Mining Rights, Buildings, Machinery, Plant, Concentrating Mill, Railway Track and Sidings, Coal Dock, Skimpings, Slimes and Ore already won. There are two principal working shafts some 500 feet in depth, which have been in full operation until recently. The property consists of all the mineral rights in two grants or locations, embracing an area of some 20 square miles (with the exception of 116 acres already disposed of), also the surface rights of about 665 acres of said lands (of which 300 acres are within the limits of the Town of Bruce Mines).

Bruce Mines Station of the Canadian Pacific Railway, situated on the property, is 135 miles from Sudbury and 37 miles from Sault Ste. Marie. The Bruce Mines and Algoma Railway here crosses and runs down to the Lake, having a station and sidings convenient to the mines.

THE BUILDINGS, adapted to large operations, are in good condition, and consist of machine shop, fully equipped, blacksmith's shop, store houses, oil house and boiler houses, two power houses, mill offices, Manager's and Mill Superintendent's houses, boarding house, ice house, stable and dynamite magazine.

THE MACHINERY AND PLANT, which are in good running order, have an inventory valuation of $96,500.00. The concentrating mill, situated on the Lake front, has a capacity of 250 tons per day and pumping plant of 60,000 gallons per hour. Its construction and equipment cost $130,000.00. The Electric Light plant has a capacity of 500 lights. One and one half miles of Railway Track (with sidings) connect the mine proper with the Concentrating Mill and Coal Dock, where vessels drawing 16 feet can load and unload.

THE SKIMPINGS, estimated at 120,000 tons, are useful for fluxing purposes in nickel smelters, and for the manufacture of artificial stone. A separate tender for these skimpings will be considered. The ore already won and in the stopes is estimated at 9,000 tons. Considerable development work has also been done on the property exposing a large body of ore.

PARCEL 2

TOWN AND PARK LOTS, containing about 300 acres within the town limits, sub-divided into over 100 convenient building lots.

WATER LOTS, situated in front of the Concentrating Mill and adjoining the coal dock.

ISLANDS : "French," "McCoys," "Bruce," "Rat," "Mouse," having in all an estimated area of 75 acres, with some suitable lumber-mill sites.

PARCEL 3

RANGE LOTS, consisting of about 365 acres in the Township of Plummer Additional.

PARCEL 4

WHARF AND WAREHOUSES, conveniently situated adjoining the Government Dock, with 16 feet depth of water.

Tenders for separate lots and islands mentioned in parcels 2 and 3 will be considered.

The principal workings are being kept free of water and will be open for examination by intending purchasers. Full descriptions and particulars of the real estate and full details, inventories, etc., of the plant, machinery and other assets of the Company can be obtained upon application to the Liquidators—T. Hayes Sheen, Jnr., at Bruce Mines, Ont., or R. C. Jennings, 18 Toronto Street, Toronto. A full inspection of all the property may be had at any time.

As to the real estate, it is understood that the foregoing description is only a general description and the areas given are only approximate and the purchaser is to satisfy himself as to the quantity of land and the title of the Company thereto and shall search the title at his own expense and the liquidators will not be required to furnish any abstract of title or to produce any title deeds other than those in their possession.

TERMS OF SALE: 10 per cent. cash; 40 per cent. within 30 days, and balance within 60 days, with interest at 7 per cent., secured to the satisfaction of the Liquidators. The tenders must be accompanied by a marked cheque, payable to the Liquidators for 10 per cent of the amount of tender, which will be returned if tender is not accepted.

The highest or any tender not necessarily accepted.

The other conditions of sale are the standing conditions of sale of the Court as far as applicable

For further particulars and conditions of sale, application may be made to either of the above-named Liquidators or their Solicitors.

DATED at Sault Ste. Marie this Third day of July, A.D., 1908.

F. W. JOHNSON, Local Master.

HEARST, McKAY & DARLING, Sault Ste. Marie, Ont.
Solicitors for Liquidators.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

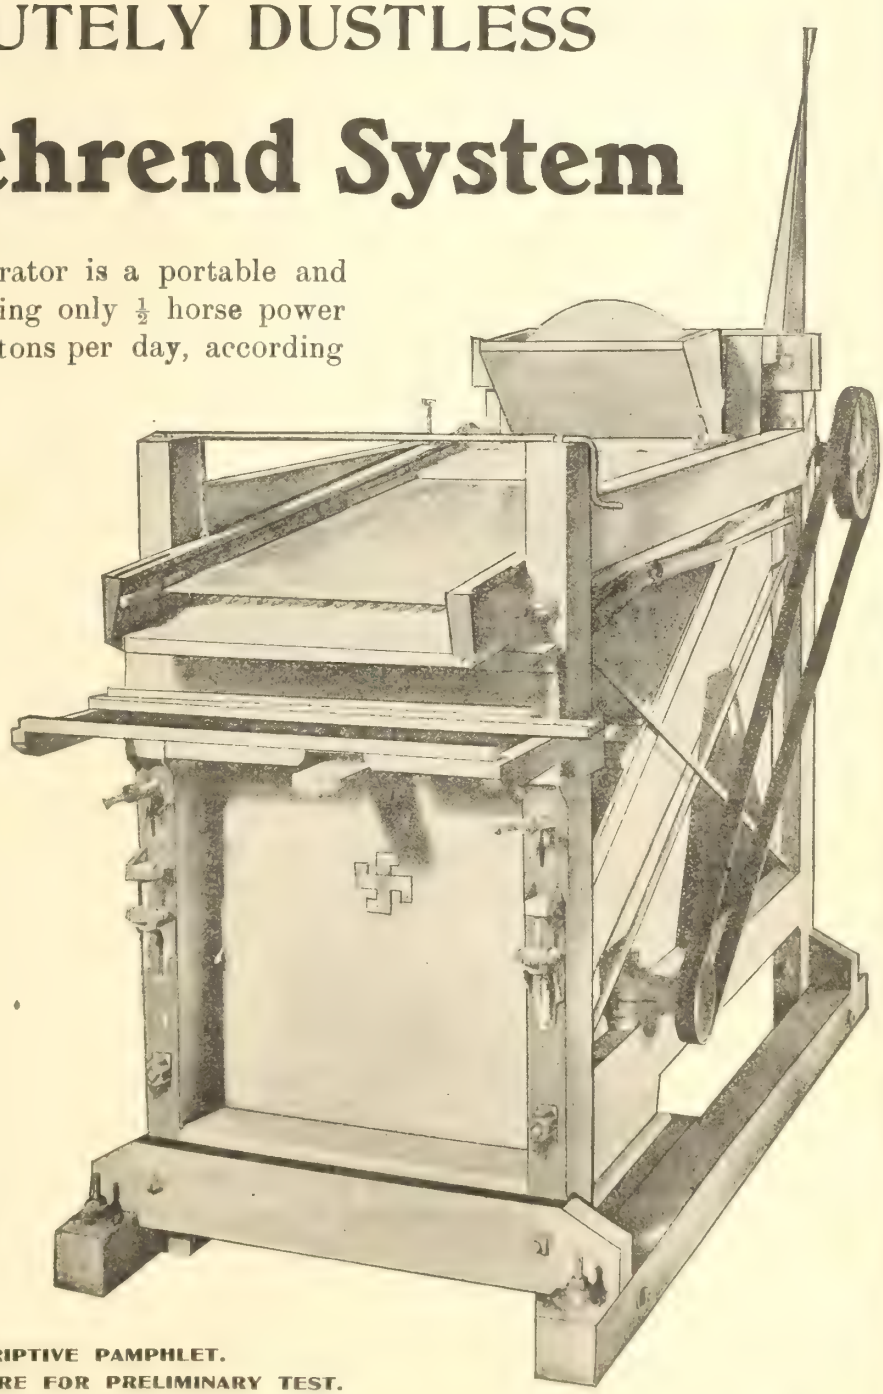
Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System



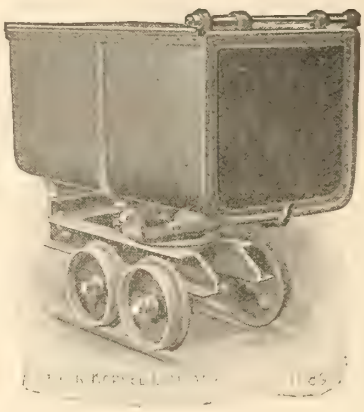
The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.



WRITE US FOR DESCRIPTIVE PAMPHLET.

SHOULD MINING ENGINEERS ADVERTISE.

"Should Mining Engineers Advertise" is the title of a clear editorial exposition in the current number of the London Mining Journal. This is a question on which an English point of view is particularly valuable. In Canada we have a considerable body of mining engineers and mining geologists whose work will stand comparison with that of engineers from any other country. But neither our mining societies nor public opinion enforces distinction as between qualified men and charlatans. Whilst it is permissible for a Canadian mining engineer to insert a professional card in technical journals and in newspapers, it is recognized as distinctly bad form to seek louder means of attracting attention. For mining men of the lower grades the inspired newspaper interview is one of the chief means of advertising. Others, again, allow their names to be used on obnoxious prospectuses. Against both these latter devices self-respecting engineers set their faces. It is, then, probable that the limit marked for Canadian mining engineers is the professional card.

Our London contemporary, however, points out that "the mining engineer . . . is not assisted by analogy from other professions, and the question is one that must be decided upon its merits, as it affects the mining profession simply." After reference to the many indirect means of keeping one's name before the public, our contemporary alludes to the fact that the mining engineer, who has worked successfully in foreign fields, may be entirely forgotten by the very people at home to whom his services would be most acceptable. This opens up the way for a revision of the code.

Our own opinion is strongly opposed to countenacing anything but the most limited advertising. Attempts to establish a laxer code of professional etiquette must inevitably lead to demoralization.

This restriction may seem a hardship to the struggling engineer. But there remains a clean and profitable channel of publicity. A professional card does little more than actually remind the readers of public that a certain engineer is alive. But a signed technical or descriptive article, appearing in a suitable publication, places the author at once in a position of more or less prominence. If the article deals with mining or metallurgical problems encountered and overcome, and if is written simply and honestly, it constitutes the best possible introduction to that section of the public with which the engineer wishes to form an acquaintance. Moreover, the man who writes an article is, obviously, willing to risk the judgment of his fellows. Therefore a certain amount of confidence in himself (always a healthy symptom) is implied.

There is yet another equal benefit accruing to the engineer who takes thoughtfully to print. Writing clarifies the mind as nothing else can. For many it is a painful discipline; but discipline it is. The making of a well-written article involves looking up many references and consulting with as many professional friends as are available. Also the mere act of crystallizing one's thoughts on paper tends to fix what is essential and to delete what is superfluous.

Therefore we would urge Canadian mining engineers to form the habit of transferring their experience to paper, either for the purpose of publication or as a record for personal reference, or, better, to serve both these ends.

We have urged this before. Our contemporary's able editorial lends us a cogent argument wherewith to impress our point more deeply.

ONCE MORE A BOOM.

There is a tendency in well-informed circles to attribute the present boom in Cobalt stocks to the skilful tactics of certain Toronto and New York interests. That well matured plans have been formulated and carried out has been patent. Specialists in publicity, when retained by stock manipulators, do not hide their searchlight under a bushel. But, although these fluent gentlemen have undoubtedly assisted in precipitating the movement in stocks, there were other influences, far more potent, at work.

One of these was the fact that ore shipments from Cobalt during the first eight months of 1908 were greater by 4,211 tons than those for the corresponding period of 1907. The totals stand 13,217 tons for the first eight months of 1908, and 9,006 tons for 1907. If, as is probable, shipments continue at this rate, the total tonnage for 1908 will reach 20,000 tons, an increase of about forty per cent. over the preceding year. Moreover, it is possible that this tonnage may be increased, as the monthly returns have lately been growing consistently.

Last year the value per ton of ore shipped from Cobalt was approximately $500. There is reason to believe that the ore being shipped at present is worth slightly more per ton than this. The recognized tendency of shippers to concentrate before shipping, and the bonanza character of ore from several of the mines, support this belief. Arguing from such grounds, it is apparent that at the close of 1908 Cobalt will have an annual output worth at least $10,000,000 to her credit.

This is, naturally, a pleasant fact to contemplate. It means that steady, serious, and honest work is being done at most of the producing mines. But it also means that Cobalt is quite able to stand on her own merits. There is, therefore, no need of a flourish of trumpets. Indeed, Cobalt, as a reputable mining town, one that has already cleaned out much of the disreputable element that clings to the skirts of new and prosperous mining communities, does not welcome the boomster.

If we read aright the signs of the times, a general reaction in the direction of better conditions is setting in. The London Stock Exchange is witnessing a rapid appreciation in South African mining shares. Activity in our own mining stocks is apparent in New York, Montreal, and Toronto. These movements could not have been entirely caused by manipulators. But, especially in this country, they can be caried to an illogical and harmful extreme by men who can command the assistance of our venal daily papers.

The public should have learned its lesson two years ago. Probably it did not. Probably, also, a boom once started will not lose its momentum until grave mischief has been wrought.

In all stock excitements the public is the chief loser. When the wave of recklessness recedes the mining industry is invariably found to be in a worse condition than it was before the boom commenced. Therefore it is the duty of all those who have the good of Canada's mining industry at heart, who wish to see our mines and smelters firmly established in the confidence of the people, to do what they can to offset the extravagant methods of imported promoters and their hirelings.

We have all the elements of success. We have rich mineral deposits, capable mining men, good markets, and, in the main, honest government administration. Our progress to be constant must be reasonably slow. There is nothing to be gained by brain-storms.

ONE COMPANY.

To mark their interest in the visit of the Canadian Mining Institute to Nova Scotia, the directors of the Nova Scotia Steel and Coal Company issued a pamphlet in which is given a most interesting history of the beginnings and growth of their enterprises together with an account of the present condition of their plants and mines.

This is not only sound policy on the part of the Company, but is indicative of enterprise and enlightenment. The visitors, who represent the best mining interests of Canada and Europe, were deeply impressed with what they saw in Nova Scotia. But a record of the quiet and efficient development of the Nova Scotia Steel and Coal Company's undertakings is unquestionably more impressive than a mere inspection of their plants and mines in operation. When it is more fully understood that industries should be based upon organic growth and not upon the speculative hankerings of the public, then we shall have more business ventures and fewer incubated indiscretions.

The Nova Scotia Steel and Coal Company had its beginnings in a blacksmith's forge. To-day there are 4,200 men on its payroll. It owns and operates its own iron and coal mines, and pays dividends.

A PERVERSION.

Nothing could be more distasteful to the British and European delegates and to their hosts, the members of the Canadian Mining Institute, than to know that their visit to Cobalt or any other camp could be used by writers in the daily press for the purpose of influencing the stock-market. The summer excursion of the Institute had an object entirely remote from this. In fact it is not overstating the case to say that such excursions are planned as a corrective to the evil that stock-jobbers have already done.

We therefore feel called upon to resent certain paragraphs appearing in Toronto newspapers in which the statement is made that "the mining engineers' visit to Cobalt . . . will have a favourable influence upon market values."

THE CANADIAN NATIONAL EXHIBITION.

In the early months of this year the CANADIAN MINING JOURNAL called the attention of the management of the Canadian National Exhibition to the need of paying more attention to the mining industry. The result has been that five Provincial governments sent along mineral exhibits. Two of these provinces, Nova Scotia and Ontario, despatched full and representative collections of their economic minerals. Quebec, New Brunswick and Alberta exhibited on a smaller scale, but all of the display was most interesting.

On another page will be found an acount of the several features of the mineral exhibit. It marked a most praiseworthy attempt to round out the scope of the Exhibition.

But the growing importance of the mineral industry warrants a greater amount of space and attention. We would urge upon the Exhibition Commission that the matter of erecting a special mining building be taken into immediate consideration. The need is pronounced for suitable housing for mineral exhibits and mining machinery.

ACTS AND THE MAN.

The Lemieux Conciliation Act has become an instrument of no little importance. Whatever its present deficiencies may be, its provisions are sufficiently flexible to permit of its successful application to many different species of industrial disputes. Its operation has proved one thing, however, that cannot be overlooked, and this is that much depends upon the wisdom of the chairman.

Professor Adam Shortt, late of Queen's University, now translated to an official billet at Ottawa, won rapid fame as an arbitrator. Peace, perfect peace, followed him as a river follows its channel. Urbane, dispassionate, incisive, his skilful diagnosis was followed by simple and proper remedies. Our body politic is the better for his work. Canada would be the gainer were Mr. Shortt a fixture on all Conciliation Boards. But this is not to be. Ottawa, with its precedence and piffle, its gold lace and guff, its functions and futilities, has swallowed our peacemaker.

THE SUMMER EXCURSION OF THE C. M. I.

In our Special Correspondence columns appears a short account of the visit of the Institute and its guests to Nova Scotia. In later issues the remainder of the journey will be dealt with.

The Mining Society of Nova Scotia spared no pains to give its visitors a profitable time. So far as the Toronto visit is concerned, while every member of the Committee did his utmost, most especial thanks are due Mr. P. W. Ellis, of Toronto, through whose kindness and enthusiasm a complete inspection of the power plants that centre around Niagara was made possible.

Thanks also to the Canadian National Exhibition Commissioners the visitors were well entertained while in Toronto.

In all things the excursion has been undeniably pleasant and successful.

WHY NOT INCLUDE THE EAST?

The Hon. William Templeman, Minister of Mines, accompanied by the Acting-Director of the Geological Survey, Mr. R. W. Brock, has completed a tour of the mining regions of Alberta and British Columbia. Bellevue, Coleman, Hillcrest, and Frank were visited in Alberta. Fire-stricken Fernie was touched, and southeastern British Columbia pretty well covered. No doubt the Minister and Mr. Brock, in whose hands lie in large measure the guidance of the Dominion's policy in these matters, will have acquired many new and useful facts. The Western Provinces may count upon added interest being taken in the growth of their mining interests.

We may suggest that a similar visit to Quebec and the Maritime Provinces would be timely.

In bridges and other structures of iron or steel, it often happens that some one of several parts in tension does not support its share of the load, and instead of the usual expensive and troublesome plan of taking down the parts and forging them in a blacksmith shop, Hasenkamp, a German engineer, purposes making the adjustments in lengths with the structure intact. His plan is to use thermit for heating the part in place. This material, a mixture of iron oxide and aluminum, is readily ignited, and it burns with an intense heat—which may reach 5,000 deg. F.—through the affinity of the aluminum for the oxygen of the iron oxide. Clamps are fastened to the steel part on each side of the spot to be heated. These clamps are connected by bolts, and when the right temperature is reached turning the nuts shorten the steel permanently to the extent desired. The operation, requiring but a few minutes, does not interfere with traffic.

AN INTERESTING OCCURRENCE OF SCHEELITE IN NOVA SCOTIA.

By A. L. McCallum.

Early this summer, while engaged on some work in the Moose River district, I was shown a small sample of a yellow mineral in quartz, which had been found the previous autumn by Messrs. Reynolds & Currie, of Moose River.

I must confess that at first sight I did not recognize the mineral, and not having the means at hand for testing it, I laid it to one side.

Shortly after this Dr. T. L. Walker arrived in Moose River, looking for occurrences in Tungsten, in association with the Nova Scotia gold ores. Together we tested this mineral, and pronounced it Tungstite. Later, on coming to make an anlysis of the mineral, I found it to be scheelite, partly altered to tungstite, the two minerals being present in nearly equal proportions.

I suggested to the finders that further search be made in the section where this was found, which was done, and resulted in the finding by Mr. Reynolds of several more pieces of quartz carrying tunsten.

I then recommended the taking up of the property under a prospecting license, which was done, and active prospecting commenced by Mr. Reynolds.

At first, search was made for the yellow altered mineral, but up to the present no more of this has been found.

Soon after starting prospecting, however, a boulder of nearly pure unaltered scheelite was found in the bed of a small brook. Subsequently a considerable quantity of drift was found in this brook, and i na larger one 600 feet further west.

At this point I wish to pay a justly merited tribute to the thorough, systematic, I was almost going to say scientific, manner in which Mr. Reynolds conducted the prospecting operations, with the result that two weeks after the first boulder had been found the vein from which it came was located and opened up in several places.

This is the vein on which, up to the present, most work has been done. It has been traced east and west for a distance of over 600 feet, and two small trial pits sunk on it, from which over two tons of ore have been taken. An average sample of this ore yielded the following result on analysis:—

Silica	29.29%
Tungstic acid (WO_3)	44.10 "
Lime	12.70 "
Arsenic	3.43 "
Sulphur	1.46 "
Oxide of iron and alumina	7.70 "

The vein occurs in a slate belt 3½ feet wide, between whin walls, dipping north at an angle of 75 degrees. The vein is situated on the foot wall, and occurs in a series of lenses of varying sizes. These lenses are of all sizes from seven inches down, and will average about three inches. The scheelite is intimately mixed with the quartz, and is evidently contemporaneous with it. There is also generally some mispickel present.

Frequently lenses of pure scheelite are encounferd. An anlysis of this yielded the following figures:—

Tungstic acid	79.84%
Lime	20.11 "
Specific gravity	6.10

The slate near the vein is heavily impregnated with crystals of mispickel, while that towards the hanging wall is practically free from it.

South of this vein four others have been located, running parallel to the first. Two of these are about the same size and quality as the first, and the other two are larger, 12-14 inches, and of lower grade, the scheelite occurring on the outside of the vein, and seems not to have penetrated to any great distance.

Quite recently some rich drift has been found north of the first-mentioned vein, thus indicating the presence of still another vein. As the glacial striae at this point runs almost direct north and south, I think it is safe to conclude that the vein from which this drift came is north of the point at which the drift was found.

I thought that this occurrence was of sufficient interest to warrant the foregoing brief description. It is the first time in Nova Scotia that a vein has been discovered in which the predominating mineral is scheelite. There was, I believe, an isolated occurrence of scheelite at Malaga, but not in convenient quantities.

There is no reason that I can see why it should not be found in some of the Nova Scotia gold districts, as there is no evidence of anything out of the ordinary in the formation when this scheelite occurs. The fact probably is that the mineral has been overlooked, as the only characteristic that would draw attention to it is its high specific gravity. In appearance it looks exactly like the calcite that frequently occurs associated with the quartz.

I have frequently had to test samples this summer before I could be sure whether they were calcite or scheelite.

UNIFORM AND SYSTEMATIC COAL MINE SAMPLING.

In "Contributions to Economic Geology," published by the U. S. Geological Survey, J. S. Burrows takes up the question of uniform and systematic coal mine sampling.

The tendency in coal mine sampling is to secure samples that are much cleaner than the coal as it is mined. Thus the sample does not correspond to the commercial product. Exhaustive tests, covering a whole year's work, show that the usual method of mine sampling cannot be relied upon to represent the average commercial product of the mine.

One of the important features of the work of the Survey's fuel-testing plant at St. Louis was the careful sampling of carload lots, and the checking of each car by means of comparison with corresponding mine samples.

The cars of coal were unloaded into a roll crusher with the rolls set 1½ inches apart, the coal falling into the boat of a bucket elevator. As the buckets of the elevator moved upward to the storage bin a sample was taken by a man with a small shovel from about every eighth or tenth bucket. This was continued until the car was emptied. The sample in a tightly covered iron bucket of 80 to 100 pounds capacity was sent to the laboratory, and there pulverized and quar-

tered down to requisite size. This method gave the most uniform results.

In mine sampling the sample was crushed in the mine immediately after taking it, thus ensuring no loss of moisture, as in the mine atmospheric conditions are generally constant.

Two or more places were selected at widely separated points on the mine where the coal bed had an average development, and from which most of the coal was being mined for shipment. At one of these places the face was cleared of burned powder, loose coal and idtr for about five feet, and insecure pieces of the roof were taken down to prevent their falling into the sample. Then a waterproof blanket was spread on the floor of the mine close up to the face, and a perpendicular cut from floor to roof was made, including everything in the sample, except the parts of the bed discarded by the miner. Sufficient coal was cut to make not less than five pounds to the foot in height—that is, a sample weighing not less than 20 pounds would be cut from a 4-foot bed of coal, and a sample weighing at least 30 pounds from a 6-foot bed. When shale or other partings were to be included in the sample, great care was exercised to cut them the full width and depth of the groove, in order to preserve the proper proportion of coal and extraneous matter. After sampling, a careful measurement was made of the vertical section of the bed, every parting and variation being noted, and those not included in the sample being clearly shown. This formed a valuable check on the value of the sample.

The cuttings were at once weighed and then sifted through a half-inch mesh screen. The remaining lumps were broken on a portable buckboard and the entire sample put through the screen. After thorough mixing of the sample in the blanket it was quartered down to suitable size. It was then spread in a circular mass about two inches deep, and with a small trowel the mass was carefully sampled. The sample, being placed in a can, was hermetically sealed with insulating tape and despatched to the laboratory.

The entire operation was carried on with as great rapidity as practicable, so that there would be little or no loss in moisture.

From systematic tabulation some interesting general conclusions were arrived at and empirical factors adduced for correcting the results of the analysis of mine samples.

For instance, run of mine moal containing less than 5 per cent. moisture will, under normal conditions, gain moisture when exposed to the weather, and if the percentage of moisture in any mine sample of such coal be multiplied by the co-efficient 1.10, the probable amount of moisture in commercial run-of-mine will be found. Coals containing more than 5 per cent. moisture in the average mins sample show a decided loss of moisture in the car samples. The co-efficient for this class of coal is 0.93.

For coals containing less than 3 per cent. sulphur the co-efficient is 1.07. For correcting mine samples of coals containing more than 3 per cent. sulphur the co-efficient is 1.05.

Similarly, for correcting a determination of ash in mine samples of coals containing less than 7 per cent. the co-efficient is 1.618, and for coals whose ash exceeds 7 per cent. the co-efficient is 1.283.

These figures are all for run-of-mine coal. Co-efficients were determined for screened and slack coal also. The following table gives all of these:—

Co-efficients for Correcting Mine Samples Approximately to Commercial Coal.

Moisture—	
For run-of-mine coal with less than 5 per cent. in mine sample	1.19
For run-of-mine coal with more than 5 per cent. in mine sample	0.93
For screened coal (lump, egg, nut, etc.)	0.97
For slack coal	1.30
Sulphur—	
For run-of-mine coal with less than 3 per cent. in mine sample	1.07
For run-of-mine coal with more than 3 per cent. in mine sample	1.06
For screened coal	1.10
For slack coal	(?.0.90
Ash—	
For run-of mine coal with less than 7 per cent. in mine sample	1.62
For run-of-mine coal with more than 7 per cent. in mine sample	1.28
For screened coal	1.37
For slack coal	1.86

METHODS AND MORALS.

ALEX. GRAY.

The financial page of the Globe, Toronto, a journal ordinarily careful, yet unwilling to forego reading matter advertisements of very doubtful origin and purpose, contains the following among other things with special reference to Larder Lake district mines:—

"CANADA'S CHANCE. If Canada would only assist her miners by liberally investing in the stocks of her own good mines, or, in other words, finance the development of her own mines, she would soon be one of the richest countries in the world. But unfortunately her people lack to a great extent the knowledge, the money and the courageous enterprise necessary. Consquently millions, yes, hundreds of millions, of our own native wealth go to swell bank accounts of other countries. Is not this deplorable? Take, for example, the case of some of the mines at Larder Lake. Half a million dollars would put any one of these wonderful discoveries in a position to turn out by stamp mill and cyaniding process tens and even hundreds of millions of dollars of our native gold. However, if the general public had the knowledge and enterprise, I believe this money shortage would be overcome to a very favorable extent. But let Canada not lose sight of the fact that although some of her mines have failed, she has many of the best mines in the world, and many yet awaiting the assistance of investment.

"Wake up, Canada, ere your gold, silver and other valuable mines are all gobbled up by foreigners."

Because the Globe has never given its editorial sanction to what made Cobalt and Larder Lake unsavory, and for the further reason that it has refrained from questionable tactics so characteristic of some of its contemporaries,* the utilization of its financial page in the manner quoted has occasioned adverse comment. Not that Larder Lake ventures can be resuscitated by such ludicrous fanfaronades, or the despised "Sassenach" and "foreigner" influenced either way by crude tarradiddling. To the contrary, the palpable object has defeated the attempt. Alien ownership will be welcomed, since Canadians of wealth are really alienated from worthy mining ventures by reckless touts. Consequently, the volume of Canadian business in the Northern Ontario district shares is insignificant in comparison with that of the American, British, and German "foreigner," and were it otherwise, were Dominion capitalists relied upon to do the "gobbling" there would be "For Rent" signs on mining brokers' offices and little but snowballs on brokers' menus. The despised "foreigner," therefore, is not in the disfavor alleged, unless it be for his tardiness in not "gobbling" more of "the lemons" and leaving promoters the equivalent in cash—the kosher.

To "wake up" with "millions, yes, hundreds of millions," of "native gold" would not "swell" anything but the membership of violent patients in institutions for the incurably insane. Canadians have not heretofore been suspected of "lacking to a great extent the knowledge, the money and the courageous enterprise necessary." Larder Lake advocates might take issue with the discretion exercised by their compatriots, but of the latter's "knowledge" in this particular instance there can be no dispute. They "know;" they have "the money," and they have "the courage" to keep their money—until papers like the Globe voice the opinions of responsible engineers and veto the vapourings of the viciously *soufflant*.

Practically every mine at Cobalt was found by a Canadian. That "the foreigner" of England and the States was requisitioned for his money or to "wake the market" is no proof of ignorance or cowardice. The three great precious metal mines—the Leroi, St. Eugene and the La Rose—were discovered by French-Canadians. That they are held in the States and in England is no argument why "half a million" should be airily experimented with. Perhaps Canadians might have made more had long-distance telephone communication between New York, Buffalo, Syracuse and elsewhere been less convenient. Maybe Canadians were wise to take wholesalers' figures and leave it for others to make profits on "the turnover." Canada has benefited. The mining industry has its colicky features and teething troubles withal, but if "the foreigner" had "gobbled" more of Larder Lake and less of merit at Cobalt, mines and moose pasturage in the markets as mineralized areas, would be worth about fifty cents a mile for some time to come. However, Canadians have their share of shipping mines, courage and cash without recourse to the "hundreds of millions" in solution, *vide* the following:—

Is it possible that Canada is bereft of common sense in preserving the equilibrium at Sudbury, Cobalt, Copper Cliff, Doloro, Thorold, Perth Amboy and Denver, and leaving "fly belt" "multi"-millionaires to become maudin? Leave it to the Globe to decide!

*EDITOR'S NOTE.—We cannot agree with Mr. Gray's statement. The *Globe* has probably done more harm than any of its contemporaries because its pretensions are greater.

METHODS OF CONCENTRATION AT COBALT, ONTARIO

By Geo. E. Sancton.

Paper read at Cobalt Branch Meeting of Canadian Mining Institute, May, 1908.

At the present time there are three concentrators in active operation in the Cobalt Camp; namely, those at the Buffalo, the Cobalt Central and Coniagas Mines. In addition has been established an experimental mill at the McKinley-Darragh-Savage Mines of Cobalt, not at present in use, and the Muggley concentrator, a customs mill which is not yet in readiness for operation. All of these plants are wet concentrators, in contradistinction to those in which the ore is concentrated in a perfectly dry state. Of this latter class of mill there is one in the camp—a custom concentrator which has not yet been put into service.

In a great many respects all of the three first mentioned mills employ the same method of treating the ores from the mines. The veins in the camp being comparatively narrow, none of the mines are able to so mine their ore that the underground work is done in vein matter only. At the mines in which the concentrators are installed, it is the custom to make in the mine a rough separation of the high grade ore from the rest of the material. This high grade ore is hoisted to the surface and sacked, as on account of its richness it needs no concentration. The remainder of the material is composed of a mixture of high grade ore, rock and ore of low values, and is hoisted and sent to the mill without any further picking or sorting. From this point the methods of treatment vary slightly in the different mills. The following is an outline of the

manner in which the ores are concentrated in the three mills which are now working, and of the proposed method of treatment at the Muggley concentrator.

The Buffalo Mine.

The ore to be concentrated is lifted from the underground working to a trestle, from which it is trammed directly in, over the main ore bin, at the highest point in the mill, and dumped over a 1″ space grizzly, which removes some of the fine material, which it is unnecessary to pass through the coarse crusher. Passing through the main crusher, which is 6 x 20 Blake set to reduce ore to about ⅞″ size, the ore is elevated to a revolving trommel fitted with three sets of screens. These screens are of perforated metal with ⅝, ½ and ¼″ holes respectively. Oversize from the ⅝ screen and the product of the 1″ grizzly pass on to the fine rolls, which are spring rolls 20″ diameter by 20″ face. The materia lunder ⅝ and over ½″ and the material under ½″ and over ¼″ is treated separately on 3 compartment Hartz jigs. The material under ¼″ passes over an impact screen fitted with 20 mesh wire screen, the product over the screen going to a third Hartz jig and the fines through the screen going to cone settler and thence to a Wilfley table. The middlings from this Wilfley table are returned to the table; the tailings are split up, the coarser portion being treated on a Deister slime table.

The tailings from all the jigs feed into a six-foot Chilian mill and are reduced so as to pass through a 20 mesh slotted screen. The product of the Chilian mill passes over an impact screen fitted with 80 mesh wire screen, which removes the greater portion of the slimes, to be treated on a Deister slime table. The material which passes over the 80 mesh screen is fed on to four Deister tables, the tails from which, being of low value, go to the dump. These tails may later on be further treated by the cyanide process if sufficient silver remains in them to warrant it. At the present time about 40-50 tons of ore are being treated per twenty-four hours, the capacity of the mill being limited by the fine rolls. With fine rolls of greater capacity the mill would handle over 75 tons per twenty-four hours, provided more concentrating tables were insalled also. The amount of ore treated in a given time varies greatly, as ores from some parts of the mine will go through the mill much more quickly than ores from other parts. A Corliss engine of 150 h.p. is used in driving the machinery.

The Cobalt Central Mine.

The ore is trammed directly from the mouth of the shaft to a large bin from which the main crusher, a 10″ x 10″ Blake, is fed, the crusher discharging directly into the mill bin. From the mill bin the ore is fed by a plunger feeder to the roughing rolls, 42″ diameter by 14″ face, from which the ore is elevated to a 2 mesh trommel. The oversize from this trommel is returned to an oversize bin. When a sufficient quantity of oversize accumulates in this bin, the feed from the mill bin is shut off and the material from the oversize bin is fed into the large roughing rolls. The material passing through the 2 mesh trommel goes on to a No. 1 centripact screen fitted with 8 mesh screen cloth. The oversize from No. 1 centripact screen is treated on two Hartz jigs; the tails from the first are dewatered and reground by 10″ x 32″ finishing rolls, and the tails from the second are recrushed by 14″ x 30″ rolls, the products of the two sets of rolls uniting and being carried by a 7 x 12 elevator to the No. 2 centripact screen fitted with six mesh wire screens. This product, previous to being elevated, passes through dewatering screens to remove excess of water. The oversize from No. 3 centripact screen passes to one of these dewatering screens previous to being reground by the 14″ x 30″ rolls. The undersize from both the No. 1 centripact and the No. 2 centripacts feed on to No. 3 centripact screen, which is fitted with No. 16 wire screening. The oversize from this screen is reground in the 10″ x 32″ rolls, the material under 16 mesh meets the water from the dewatering screens and goes to two 20″ hydraulic classifiers and the sands from these classifiers are treated on four James tables. The overflow is settled in two Callow settlers and the thickened pulp is treated on two other James tables. The overflow from the Callow settlers, being practically clear water, goes to waste. The middlings from all six James tables are re-treated on the seventh James table; the tails from which, being of low value, go to the dump.

The mill, with average ore, is capable of handling about 50-60 tons per twenty-four hours. Of the values extracted about 70 per cent. are recovered by the jigs. In this mill all the fine grinding is done by rolls, the 10″ x 32″ rolls being set to crush to not over 16 mesh. The James tables are designed to also handle any slimes settling on a section of the table, which is left smooth and practically flat. On this section of the table most of the values in the slimes are extracted. There is, however, very little work for this part of the table to do and the quantity saved on it is not great. On the average the tails from the James table runs not over four to five ounces per ton. This mill is also driven by a 125 h.p. Corliss engine.

The Coniagas Mine.

The ore will eventually be raised from the mine in a skip and dumped directly into the mill storage bin through a long chute. Ore is first crushed in a 10 x 16 crusher, elevated, passed over a grizzly, recrushed by a 7 x 13 crusher and discharged into a storage bin. From this storage bin the ore is reduced to ¾″ by No. 1 rolls and elevated to No. 1 trommel, which has ¾″ and 5/16″ perforated steel screens. The oversize is returned to No. 1 rolls, which are 10 x 30; the oversize from the 5/16 and under ¾″ goes to two sets of Hartz jigs, the tailings from which are recrushed in No. 2 rolls. The undersize from the 5/16 screen goes to No. 3 trommel fitted with 3 millimeter screens. The oversize returns to No. 2 rolls; the product over ¼″ and size from this trommel goes to fine jigs, the tails from which go to a 5′ Huntington mill fitted with about 20 mesh slotted screens. The product from the 3 m.m. trommel, less than 3 m.m., is classified, the sands being treated on a Wilfley table and the slimes on a Frue vanner. The tails from the vanner also go to the Huntington mill. The tailings from the coarse jigs, after being recrushed in the No. 2 rolls, which are also 10 x 30, are elevated to No. 2 trommel, which is fitted with ½″ and ¼″ perforated metal screens. The over- under ½″ is ground in a ball mill fitted with about 20 mesh screen. The product from the trommel, which is under ¼″, goes to the No. 3 trommel previously mentioned. The materials from the Huntington mill and from the ball mill, crushed to 20 mesh and finer, unite and go to a classifier, the coarser product from which is treated on four No. 2 Deister tables. The tailings from the Deisters go to waste, the middlings being retreated on a Wilfley table. The overflow from the clas-

sifier goes to a Callow settling tank and the thickened pulp is treated on a Frue vanner. The mill is driven by a Robb engine of about 100 h.p. capacity.

The Muggley Concentrator.

Ore to be concentrated will be taken up the incline tramway to the top of the mill and fed into a No. 4 style K. Gates crusher. From the crusher the ore will be fed into a set of Gates economic rolls, which crush to ¾" and under. The ore will then pass over a screen with 1⅛" openings and go to a two compartment bull jig. The tails from the bull jig will be elevated and discharged by a belt elevator to the ore bins from which they will be fed by Challenge feeders to twenty 1,250 pound stamps. The mortars will be fitted with screens approx. of 20 mesh and the stamped material will be elevated to Richards annular vortex classifiers. The spigot product will be treated on four Wilfley tables, the overflow going to two 8′ callow tanks. The tails from the Wilfleys will be re-treated if found of sufficient value. The thickened material from the callow tanks will be treated on corrugated belt vanners, the tails from which will unite with the middlings from the Wilfley tables and go to 8′ settling tanks. The sands from the settling tanks will go to 8 'amalgam pans and to four 8′ settlers. The amalgam will be retorted and the tails let go to waste. It is estimated that the complete cost of treating ores in this mill will from $4.00 to $12.00 per ton. It may be found necessary to roast the ore previous to amalgamation, and if this is done it will likely reduce the cost of treatment.

When the subject of the treatment of Cobalt ores was first considered, the main difficulty was thought to lie in the prevention of the crushed material from sliming, the general opinion being that the ore would slime to such an extent that the loss of values in the slimes would be very excessive, while the actual process of reducing the ore to a fine state was not considered as being a very important one. But as a matter of fact this order has been practically reversed, as there appears to be no great trouble in getting a good extraction, though the actual fine grinding of the material has proved a problem of great importance. The coarser reductions give little trouble, as the material breaks along its fractures and, furthermore, accurate crushing to size is not altogether important. When it comes to the fine grinding, the rock is particularly difficult to reduce. The small particles seem to be exceptionally hard and the wear on the roll shells, or Chilian mill tyres, as the case may be, is very great, grooving taking place to such an extent that the capacity of the machines in the case of the Chilian mills and the capability to give a fine product in the case of the rolls is greatly reduced.

In connection with the fine grinding there is one mill, the erection of which is contemplated, in which it is proposed to use stamps. This method has much to recommend it. The cost per ton of ore crushed would not likely exceed 30 to 40 cents per ton, and this we do not think can be bettered by either fine grinding with a series of rolls or with Chilian or Huntington mills. To drive either of these machines a much greater horse power is required and the upkeep is more expensive both for parts and the amount of labor required to keep the machines in order. Half a day's work on a small stamp battery putting in new liners and refitting with new shoes and dies will make the battery practically as good as new. To overhaul a Chilian or Huntington mill thoroughly would probably take over a week at the least. Some silver would no doubt accumulate in the mortar boxes, but this would be no serious disadvantage as it could be easily and quickly cleared out as often as was found necessary.

The assertion has been made recently by one of the mine operators in Cobalt that stamps have no place in a concentrator. This statement, in the writer's opinion, is very broad and possibly rash in view of the number of stamps working with apparent success in many parts of the world. His statement, it is understood, covered milling in general and not only the reduction of Cobalt ores. The success of stamps in general as a crushing medium has been well shown at the Michigan Copper Company and other properties in the Lake country. For the fine crushing in connection with the treatment of the jig tailings on tables, we think that stamps will ultimately prove to be the best device.

The treatment of the tailings from the concentrating tables from the various mills by the cyanide process is a matter which is open to a large amount of discussion. In Mexico this has certainly proved a success, but the conditions in that country are much more favorable than those in this district. Unless the tailings carry much higher values than is said to be the case, it will require very cheap treatment to justify the installation of the cyanide plants for the treatment of tailings solely. In Mexico the climatic conditions are more suitable, and the cheapness of labor also bears a strong influence on the success of the process. There the operations are largely in the hands of mining engineers from the Rand, who, having seen the great success of cyaniding in South Africa, have carried their ideas to Mexico, and introduced them there in the treatment of silver ores.

In the Republic Camp, in Washington, they are treating an ore in which the values of silver and gold are about the same. It is found that the gold is easily leached out, but that the recovery of the silver is a matter of three or four days.

The actual extraction that would ultimately be made on the tailings here in Cobalt by the cyanide process is not questioned, but it will be at the expense of a large consumption of cyanide and the leaching out will be very slow on account of the comparatively large pieces of silver—large by comparison with the minute state in which gold is disseminated through the low grade ores in the Rand—which will require to be dissolved. At a great many of the mines in Cobalt, chalcopyrite is found to some extent and it would all mix with the ore going to the mills. This, when it finally reached the cyanide tanks, would tend to increase the consumption of cyanide. The question, however, of the actual success of the cyanide treatment here will largely depend on whether the tailings are sufficiently rich to stand the cost of treatment.

In connection with the primary crushing of the rock in most of the mills now running, and in most of the mills whose erection is contemplated, the Blake type of crusher seems to be preferred in preference to the gyratory crusher. In the Blake crusher the wear is practicall yconfined to two points, that is to say, at the lower ends of the jaw and wearing plates. For this reason the plates must be frequently renewed. In the gyratory crusher the wear is distributed over a far greater surface and the renewal of the concaves and the mantles is not necessary to the same degree. For a given amount of ore crushed the power taken is less; and, furthermore, the crusher head having a circular

motion in contrast to the reciprocating motion of the jaw in the jaw crusher, the strain on the supports for the gyratory is not nearly so great; and in case where the crusher is located in the upper part of the mill building the shaking and vibration due to the crusher is far less. This would enable the upper portion of a mill building to be made lighter, as it would not have to be so strongly braced to hold the crusher from oscillating.

For treating the Cobalt ores the simplest form of mill would first crush the ore to about 7/8" size in a Gates crusher. This product would then be passed over a bull jig, which to a great extent would displace the need of hand sorting. These tailings would then be crushed with rolls, roughly sized and treated on two jigs. The tailings from these jigs would then go to the stamps, so arranged that any of the tailings which were not of sufficient value to treat could be run directly to waste. The silver which accumulates in the mortars could be removed periodically, and the product after leaving the stamps, treated on Wilfley or other suitable tables and corrugated belt vanners. As the actual tonnage of concentrates produced would be comparatively small, it might be found profitable to treat these concentrates in amalgamating pans fitted with mullers for grinding. This would amalgamate a large amount of the native silver and the amalgam could be retorted and the buillion shipped. The concentrates from which most of native silver would be removed could then be shipped to the smelters and their treatment would cost far less than if the original concentrates had been shipped.

In this scheme very little mechanical screening is used, only a coarse sizing for the jigs being made. No fine jigging would be attempted on account of the leanness of the material; it would be better to allow the finer material to go direct to the stamps. Attrition of the small pieces might also be an objection to fine jigging. The extensive use of trommels, screens and other mechanical sizers, would add greatly to the costs of the upkeep of the mill as there is usually a great amount of wear attached to machines of this class. On account of the hardness of the ore milled the best and heaviest machinery on the market would be, there can be no doubt, the cheapest in the end.

NOTES FROM THE PROVINCE OF QUEBEC.

THE BROUGHTON ASBESTOS FIBRE COMPANY.

This company was the first in the Broughton district to build a mill, and has been operating continuously for over six years. The two principal pits are located along the southerly contact with the schist formation, and have now a depth of from 65 to 90 feet. The mill, which was entirely overhauled and enlarged last year, contains three cyclones, and treats from 350 to 400 tons of asbestos rock in double shift. The mill rock is transported in 4-ton self-dumping cars, and handled by small locomotives to the mill, a siding connecting also the latter with the main track of the Quebec Central Railway. The construction and layout of the mill embodies a number of effective designs and improvements especially adapted to the peculiar conditions governing the occurrence and extraction of the Broughton fibre, and are the result of diligent studies on the part of Mr. H. Williams, the energetic manager of the concern.

THE QUEBEC ASBESTOS COMPANY.

This mine has been in continuous operation since 1904, and has contributed largely to the asbestos output of the Broughton district. The main pit measures 300 by 100 feet, with a depth of 75 feet, and is located along the southerly contact with the schist formation, which strikes here northeast-southwest. The serpentine is much fissured, and little powder is used to break the rock. The fibre is the regular Broughton slip-fibre, and fills the fine cracks and slickensides of the bright green serpentine. The mill is in operation day and night, about 150 tons of rock being treated as an average, yielding from 7 to 10 per cent. of fibre. Forty-five men are employed.

THE FRONTENAC ASBESTOS MINING CO.

This company, which owns 108 acres of asbestos ground right near the station of East Broughton, is at present engaged in the construction of a 500-ton mining and milling plant. The asbestos deposit is located towards the middle of the property, and has been laid open along the southern contact of the schist formation in a northeasterly sense for a length of 600 feet and a width of over 100 feet. The mill building measures 102 by 60 feet, and the dryer building 70x40 feet. A fine piece of trestlework has been completed, upon which the receiving tracks for the mill rock will be laid. Four cable derricks are being installed, conveying the rock to dumping cars, hauled by small, geared locomotives to the ore bin of the dyer. A special feature of the mill is the ore bin, placed between dryer and mill. This bin is one of the largest in the asbestos district, its capacity being about 800 tons, and by reason of its extra solid, substantial construction on heavy concrete foundations, is favourably commented upon. Machinery will soon be installed, four cyclones will treat the rock, and the combined milling capacity will be 500 tons. Mr. H. Riehle, M.E., is the general manager of this company and the designer of the large surface plant. Thirty men are engaged in construction work.

THE BOSTON ASBESTOS CO.

This company commenced operations less than a year ago on the property adjoining the Frontenac to the east, and have almost completed a substantial 300-ton milling plant located alongside the track of the Quebec Central Railway. The main pit runs along the southern contact with the schist formation, at a distance of about 600 feet in a northerly direction from the plant. A cable derrick transports the rock to self-dumping cars on an inclined tramway leading to the dryer building. This contains a large Campbell dryer of the latest design and the necessary jaw crushers. The rock passes then into storage bins, then through a huge Sturtevant crusher, two fibrizes, and finally through two cyclones. The power plant consists of two Jenckes boiler and a straight compound Corliss engine of a capacity of 450 horsepower. A siding connects the railway with the mill. Mr. A. A. Normandin is the general manager of this company.

A recent noteworthy discovery is an asbestos deposit on lot 13c, range 5, Broughton, belonging to Mr. A. A. Normandin. This deposit is remakrable by reason of its peculiar deposition of asbestos fibre, and also its richness. A pit 15x25 feet on the surface in a highly fissured pale green serpentine discloses the nature of

the deposit; a decidedly white and silky fibre occurs abundantly throughout the rock, yielding, according to a conservative estimate, at least a fifteen per cent. extraction, besides a quantity of crude. There seems to be no question that this deposit is the richest individual occurrence in the district.

PROVINCIAL MINERAL EXHIBITS AT THE CANADIAN NATIONAL EXHIBITION.

The directors of the Canadian National Exhibition, which is the largest annual fixture of its kind in North America, have heretofore paid but little attention to securing a representative exhibit of Canadian minerals. Acting upon the suggestion of the Canadian Mining Journal the Commissioner determined to make a departure this year. To this end the Provincial Governments were approached and five of them sent creditable collections.

ONTARIO'S MINERAL EXHIBIT.

The Provinces that complied with the Commission's request were: Nova Scotia, New Brunswick, Quebec, Ontario, and Alberta. British Columbia and Yukon Territory will fall into line next year.

All of the mineral exhibits were attractive. Those of Nova Scotia and Ontario were particularly comprehensive and well arranged. Quebec and New Brunswick sent smaller consignments of minerals. Alberta's display, arranged in conjunction with that province's magnificent wheat exhibit, was composed of bituminous, coal, lignite, anthracite, coke, and briquettes. Descriptive literature was distributed by those in charge of the exhibits and there is no doubt that the mineral wealth of the provinces represented received wide advertisement.

ONTARIO.

Ontario's mineral exhibit was handled and arranged under the active direction of Mr. William Nicol, Professor of Mineralogy, School of Mining, Kingston, Ont. No more competent mineralogist can be found in Canada than Professor Nicol. Under his vigorous management the collection of minerals used at the Buffalo Exposition was augmented by important additions, and the whole was displayed with discrimination and sound judgment. It was fortunate indeed that the Ontario Bureau of Mines was able to secure the services of a

person so thoroughly enthusiastic and so unquestionably efficient.

We shall notice first the metallic minerals, and then the non-metallic, commencing, as might be expected, with the striking Cobalt ores and products.

O'Brien Mine.—From this famous mine came two slabs of native silver, and one magnificent mass of ore carrying native silver and cobalt bloom. Both of these exhibits were more than usually large and rich. The **Doloro Mining and Reduction Company,** whose smelter treats the O'Brien and other Cobalt ores, sent specimens of speiss, six silver ingots (999 fine), sample lots of dark and light crude arsenic, white arsenic crystals, refined arsenic, and cobalt-nickel residue.

Coniagas Mines, Limited, sent specimens of native silver and cobalt-nickel ores. **The Coniagas Reduction Company,** which bears the same relation to the Coniagas mine as does the Deloro smelter to the O'Brien mine, exhibited a silver ingot (998.4 fine), cobalt oxide, nickel oxide and refined white arsenic. The cobalt and nickel oxides are specimens of the first of these materials prepared in Canada.

La Rose Mines, Limited, displayed a large number of silver nuggets and four large masses of silver-cobalt-nickel ores, along with fine specimens of cobalt bloom.

Crown Reserve.—An imposing mass of native silver and calcite, calculated to contain about 33 per cent. of the metal and weighing 1,700 pounds, was purchased by the Ontario Government as a permanent exhibit. Its extreme width, as shown by the hanging and foot-wall faces, is approximately three feet, and it is typical of the Crown Reserve vein at its best. Ontario has made a good bargain in acquiring this magnificent and unique specimen. At the present low price of silver it will be a safe investment. The silver content will probably be estimated indirectly by a specific gravity determination. The specimen, in spite of its extreme bulk and weight, was ingeniously lowered upon a substantial plush-covered base and a glass show-case built around it. It is not probable that such an exhibit could be duplicated in any other part of the world.

The Laurentian Gold Mines, Wabigoon, Ont., had a rich exhibit of gold nuggets and gold in quartz, of a total estimated value of $4,000. Gold ores from other mines in western Ontario were included. Larder Lake was represented by specimens of ore sprinkled with visible gold from the Harris-Maxwell mine.

Iron Ores.—From the Bessemer mine, Hastings County, came exhibits of the fine granular, non-phosphatic ore of that region. Magnetites also from Moose Mountain and other localities were seen in this section.

Pyrite.—Specimens of the green ore, cinders and sulphuric acid prepared from the ore by the Nichols Chemical Company, Sulphide, Ontario.

Nickel and Copper.—A large and representative collection of ores, mattes, and metals from the Orford Company and from the Canadian Copper Company, Copper Cliff, Ontario. Copper ores were also exhibited from the McGowan mine, Sudbury District.

Zinc ores were displayed from the Richardson and Zenith zinc mines, Frontenac County, Ontario.

The **Canada Corundum Company** had a fine showing of crude ore of various sizes, corundum grains, and grinding wheels of different dimensions and fineness of grain, along with a collection of abrasive implements made from Canadian corundum.

Carborundum.—Samples of crystals of carborundum and various articles such as sandpaper, knife sharpeners, etc., were sent by the Carborundum Company, Niagara Falls, Ontario.

Mica.—Kent Brothers, Kingston, Ont., exhibited thumb-trimmed mica of commercial sizes, and large natural crystals. The General Electric Company, of Schenectady, N.Y., exhibited a collection of mica from their Lacey mine, Sydenham, Ontario.

Talc.—Masses of crude talc from the Henderson talc mine, Madoc, Ont., were accompanied by samples of crushed, ground, and bolted talc, prepared by Geo. H. Gillespie & Co., Madoc. This latter exhibit, from the only talc grinding mill in operation in Canada, attracted a great deal of favorable comment. Massive specimens of actinolite and soapstone from other parts of Ontario completed this section.

Gypsum.—Staff decorations and ornamental manufactured articles, manufactured from Haldimand County gypsum, by W. J. Hynes, of 16 Gould Street, Toronto, were shown in this section, along with a creditable exhibit from the Alabaster Company, of Paris, Ontario.

Portland Cement.—Samples of the raw material for both the dry and the wet processes as carried on by the Canadian Portland Cement Company at Port Colborne and Marlbank, Ontario. Also an exhibit of building materials manufactured from Portland cement by John W. Litton, Kingston, Ontario.

Graphite.—Specimens of ore from the Black Donald mine, Renfrew Ont.

Calcium Carbide.—Raw materials and manufactured products from the Ottawa Carbide Company, Ottawa, Ont.

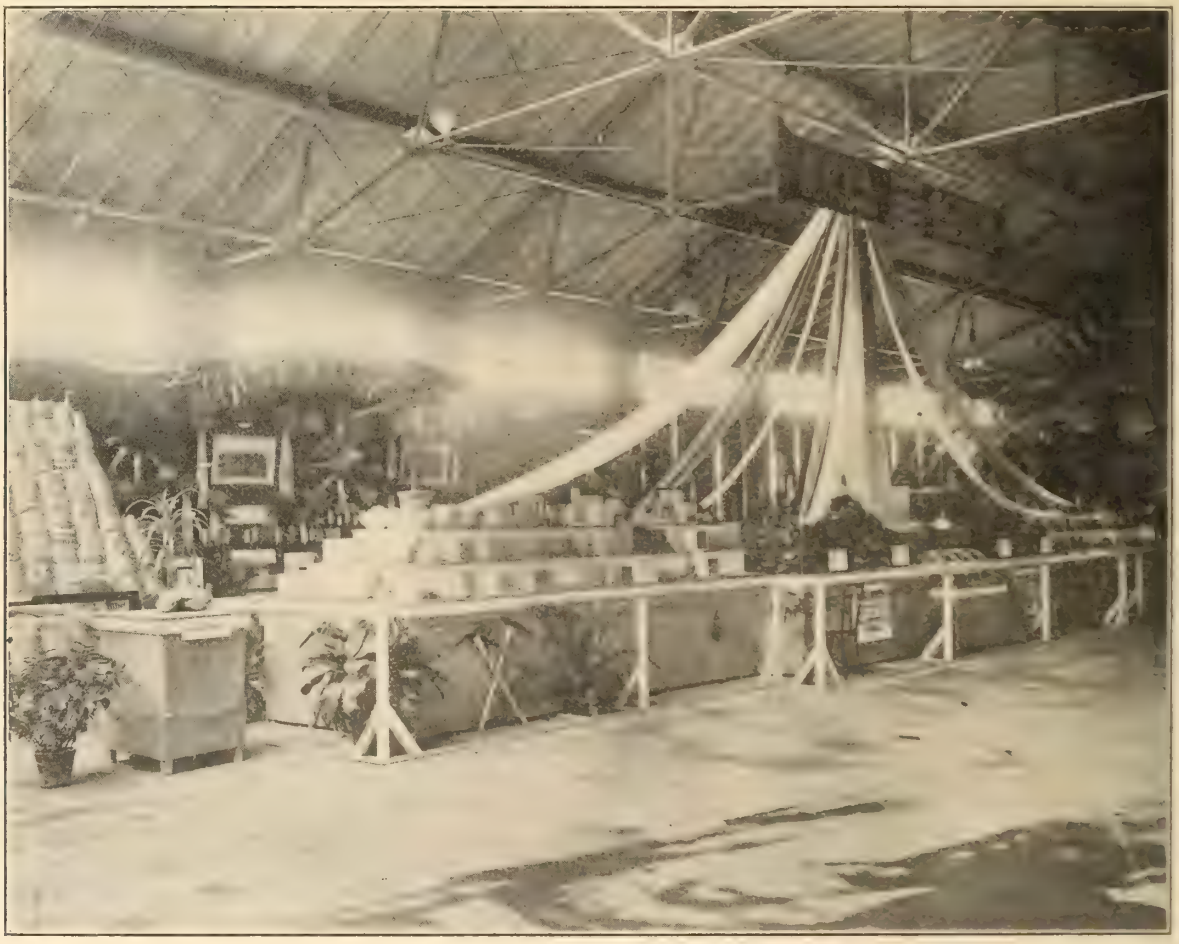
Marble.—Two strikingly beautiful slabs of decorative marble and fifteen other samples brecciated marbles were contributed by the Ontario Marble Quarries of Bancroft, Hastings County, Ontario. The unique coloring of this marble caught the attention of visitors at once.

Sodalite from Princess Louise Mine, Bancroft, and **Fluorspar** from Madoc were also included.

The **Imperial Oil Company** had a complete exhibit of oils, paraffines, etc.

An important addition to the Ontario exhibit was a collection of the typical rocks and minerals of the Cobalt District. Mr. A. A. Cole, mining engineer to the T. & N. O. Commission, contributed this. Many of the cases used by Professor Nicol belonged to the School of Mining, Kingston, Ont.

NOVA SCOTIA.



Nova Scotia's exhibit, arranged and prepared by Mr. Harry Piers, Curator of the Provincial Library, Halifax, N.S., was exceedingly well displayed. The notable variety of minerals included the richness of the gold specimens, and the substantial character of the well-designed frame upon which the specimens rested distinguished this most creditable representation. The central feature of the exhibit was a gilded column resting upon a gilded plinth, which together represented the bulk of the total gold extracted from Nova Scotia gold mines since the first discovery of the metal. From this column depended streamers and bunting.

Detailed description of this exhibit will be found on page 138 of the Canadian Mining Journal for May 15, 1907. Among recent additions to this permanent exhibit are specimens of scheelite from Moose River, Halifax County, N.S.

Both the Province and Mr. Piers deserve great credit for the energy and taste that has been used in getting together this collection.

QUEBEC.

The Quebec Department of Mines, on account of delays and pressure of other work, was unable to send a suitably large mineral collection. What was sent, however, represented the most important industries.

NOVA SCOTIA'S MINERAL EXHIBIT.

A gilded shaft from which streamers depend represents the total output of gold from the Province

Asbestos.—Large exhibits of crude asbestos and the different grades of milled product were made by the following companies: Beaver Asbestos Co., Bell's Asbestos Co., Standard Asbestos Co., Dominion Asbestos Co., Johnston's Asbestos Co. Specimens showing the mode of occurrence of the mineral were also included.

Chrome Ore and concentrates from Black Lake.

Copper Ore from Eustis Mine, Capelton.

Mica from Templeton.

Magnetic Lands from Moisie, Saguenay County.

Next year teh Quebec exhibit will be much more comprehensive.

NEW BRUNSWICK.

Iron.

Magnetic Iron Ore, Lepreau, Charlotte County. These ores occur in veins, from a quarter of an inch to eight inches in thickness, in schists of pre-Cambrian age, about two miles from the village of Lepreau. They contain 66 per cent. of metallic iron, and are free from titanius.

Magnetic Iron Ore, Deer Island, Charlotte County. The specimen exhibited is from deposits similar in age and character to those of Lepreau.

Magnetic Iron Ore, Nepisiguit River, Gloucester County. The ores of this locality, though long known, have but recently attracted attention. They are found on the left bank of the Nepisiguit River, about eleven miles from the town of Bathurst and seven from the line of the Intercolonial Railway. They occupy an extensive area, and are of good quality. They are the property of the Drummond Mines, Limited.

Hematite, Jacksontown, near Woodstock, Carleton County.

Copper.

Sulphide of Copper, Letete, Charlotte County.

Sulphides of Copper (Bornite, Chalcopyrite and Copper Glance), Simpson's Island, Charlotte County. The occurrence of copper ores on Simpson's and Adam's Island is similar to that of Letete, except for the presence of bornite and copper glance.

Sulphide of Copper (Chalcopyrite), Northampton, 4½ miles from Woodstock, Carleton County. Cobbler and Sexton Mine.

Sulphides of Copper (Bornite and Chalcopyrite), Goose Creek, St. John County. American Copper Co.

Sulphide of Copper (Copper Glance), Dorchester, Westmoreland County. These ores are peculiar as occurring in grey sandstones and conglomerates of carboniferous age, partly in the form of small veins, rarely more than a quarter of an inch in thickness, and partly disseminated through the rock in quantities not directly visible to the eye. There is also more or less of the green carbonate.

Nickel.

Nickeliferous Pyrrhotite, St. Stephen, Charlotte County. The New Brunswick ore is, like that of Sudbury, a pyrrhotite, and occurs in or partly replaces a highly crystalline diorite, probably of pre-Cambrian age.

Antimony.

Sulphide of Antimony (Stibnite), Native Antimony, Lake George, Prince William, York County. Canadian Antimony Co. of Lake George. Quite recently interest in these deposits has been renewed, considerable quantities of ore have been taken out, and the Canadian Antimony Company of Lake George (capital $250,000) is proposing to carry on operations on an extended scale. The average percentage of antimony is 20 per cent., with in some analyses from 1½ to 2 oz. of silver to the ton.

Manganese.

Manganese Oxides (Manganite and Pyrolusite), Markhamville, Kings County.

Manganese Oxides (Manganite and Pyrolusite), Shepody Mountain, Alberta, County; Jordan Mountain, Kings County; Quaco, (St. Martin's), St. John County.

Manganese Oxides (Manganite and Pyrolusite), Tattagouche River, near Bathurst.

Bog Manganese, Dawson Settlement, Albert County. The ores of Markhamville were remarkable for their richness, the best grades ranging as high as 98 per cent. of pure ore, and worth about five cents per pound, while lower grades, shipped without special treatment, brought in England $15 per ton. The ores from the locality were almost entirely used for chemical purposes. The Markhamville mine is said to have produced some of the highest grade manganese in the world.

QUEBEC'S MINERAL EXHIBIT.

At Dawson Settlement, Albert County, occurs a deposit of Wad, or Bog manganese, of remarkable extent and purity, containing by analysis about 45.81 per cent. of metallic manganese. They are therefore low-grade ores as compared with those of Markhamville, but are well suited for the manufacture of spiegel and ferro-manganese, employed in steelmaking.

Coal.

Bituminous Coal, Minto, Queens County, N.B.; Beersville, Kent County, N.B. The coal is of the caking variety, and as such is highly esteemed for black-

smiths' use. When properly screened it is also a good house coal. It is largely used upon the I. C. R., as well as for electric light works, water works and factories. It is worth, in Fredericton, from $3.50 to $4 per ton.

Albertite.

Albertite is closely related to petroleum in its properties, though differing somewhat in chemical composition. When subjected to distillation it yields about 100 gallons of oil to the ton, while the gas product was 14,500 cubic feet of superior illuminating power. It was chiefly employed as an enricher of coal gas, and was valued at from $15 to $20 per ton.

Bituminous Shale.

A considerable band of highly bituminous shales, probably of Devonian age, traverses the counties of Kings, Albert and Westmoreland, and in the vicinity of Baltimore, Albert County, assumes something of the character of cannel coal.

Quite recently renewed attention has been directed to these shales in consequence of the very succesful treatment of similar shale in Scotland, and a considerable shipment from Baltimore has been sent to the latter country under the direction of the Canadian Geological Survey, to test more thoroughly its capacity for similar treatment. The results of this experiment are not yet available in detail, but from reports so far received the prospects are very encouraging.

Petroleum.

Memramcook, Westmorland County. Not only are the bituminous shales of Albert County largely impregnated with oily matter, but at various points fluid petroleum has been found to occur in these and the associated rocks.

Graphite.

St. John. Bands of impure graphite are found, associated with Laurentian limestone, at several points afforded material for foundry facings and the manufacture of paint. They are not, however, at present being utilized. The material contains a little less than 50 per cent. of graphite carbon, but its state of physical aggregation is apparently unsuited for the higher uses to which graphite is often applied.

Gypsum.

Snow White Gypsum or Alabaster, Translucent Gypsum, Pink and Salmon-red Gypsum, Grey Gypsum,

NEW BRUNSWICK'S MINERAL EXHIBIT.

Crystallized Gypsum or Selenite, Fibrous Gypsum, Anhydrite, Hillsboro, Albert County. Albert Manufacturing Company. New Brunswick has long been noted for the extent and character of its gypsum disposits. These always occur in connection with red sediments and limestones of Lower Carboniferous age., and are found at many localities, of which Hillsboro, Albert County, is by far the most important. The plaster beds here cover a large area, and many quarries have been opened, showing faces of from thirty to one hundred feet, but without revealing the base of the deposit. The larger part of the rock is a pure white opaque gypsum of exceedingly fine grain, but with this are to be found in places all the varieties enumerated above. Anhydrite, or "hard plaster," is irregularly

distributed through or with the softer gypsum, but large bodies free from such admixture are met with. Selenite or crystallized gypsum is of rare occurrence. The analysis of the Hillsboro plaster shows 98.88 of pure gysum.

The United States duty on manufactured plaster is $2.25 per ton, and were it not for the superior quality of the Hillsboro rock, would be well nigh prohibitive.

Gypsum, Plaster Rock, Victoria County. On the Tobique River, in Victoria County, are large beds of gypsum, which have for many years been used for fertilizing purposes by the farmers of Carleton County and Aroostook County, Maine.

Building Stones.

Grey Granite, Spoon Island, St. John River, Hampstead, Queens County.

Red Granite, St. George, Charlotte County.

Black Granite (Mica-diorite), Bocabec, Charlotte County. Granite is a very abundant rock in New Brunswick, occupying large areas, and presenting several varieties.

Freestones.

Freestones, Dorchester (Budreau quarries).

Grey Freestone, Chatham (French-fort quarries).

Red Freestone, Sackville (Sackville Freestone Co., Ltd.).

Ornamental Stones.

Feldspar Porphyry, Chamcook Lake, Charlotte County.

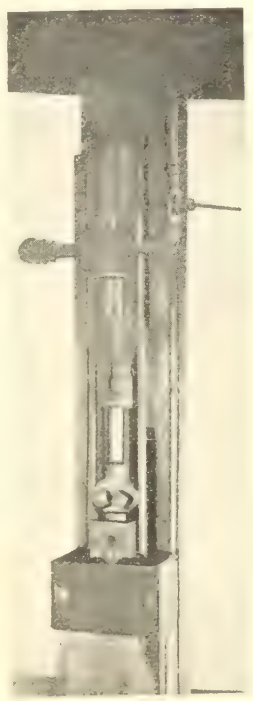
Marble and Serpentines, St. John, N.B.

ALBERTA.

The general exhibit of the Province of Alberta, whose fuel supply is now a large factor in the industrial development of the West, was handled by Mr. Richardson, the Director of the Alberta Provincial Exhibition. Wheat and coal, the two staples of the province made up most of this admirably arranged exhibit. Bituminous coals, lignites, anthracites, coke and briquettes surrounded the field of wheat. The coal specimens were of surprising size and purity. The Briquettes from Bankhead, Alberta, served as a gentle reminder that Alberta is keeping pace with the best in the conservation of her natural resources.

Drummond Mines, Limited.—Prominent among the mineral exhibits were two large pyramids of iron ore from this company's extensive deposits at Bathurst, N.B., and at Torbrook, N.S.

The Bathurst ore, a high-grade magnetite, as shipped, contained 60 per cent. iron and low phosphorous and sulphur. The Torbrook ore, ranging from 52 to 58 per cent. iron, contains about one per cent. phosphorus. These exhibits represent two of the most important iron ore deposits of Eastern Canada. Both are situated near tidewater. They will form the basis of large industries. In both localities the visible supply is enormous.



A USEFUL DEVICE.

By Fred Cotton, Sulphide, Ontario.

The accompanying cut illustrates a useful air-hammer for making drill shanks for rock-drills. The whole apparatus is simple and inexpensive.

Before hitting upon this idea I was turning shanks on the lathe. This took up so much time that this simpler method occurred to me.

I took an old drill cylinder that was of no other use on account of the feed not long having broken off; also a C. I. block 12″ x 12″ x 14″, and put the side rods through the block, leaving a shoulder on the rods between the cylinder and block. Cast steel dies, one half fastened to block, the other made with drill shank to fasten to chuck, completed the outfit.

HOME MADE SHANK MACHINE.

I also removed ratchet and rifle bar, filled the piston with babbit, slotting out the chuck to fit side rods and keep dies in position. This also acted as crosshead.

This hammer is set up on a 12″ x 14″ timber, cemented to the ground. It has been working all summer to perfection, and makes a good drill-shank in less than one minute.

Steel bands or belts, as a substitute for ordinary leather belts or rope drives, have been introduced by a factory of Charlotteburg, Germany. Such belts may be reduced to about one-sixth of the size required for leather belts, they do not stretch, pulleys may be made narrower, and in some cases may be smaller. Either ordinary pulleys or pulleys with a special covering to increase friction may be used. A belt 4 inches wide and 1-5 inch thick transmitted 200 to 250 horse-power at a belt-speed of 5,400 feet per minute, and tests have shown that steel belts may run 12,000 feet per minute.

The smoke-density meter of Edmund J. Kunze comprises a short length of one-inch brass tube, to one end of which is pivoted a revolving disc of transparent celluloid in four sections. These sections are tinted different shades of gray to correspond to densities between no smoke and jet black, and each has a hole in the centre. The observer, looking toward the smoke, turns the disc until the tint nearest the smoke is found.

THE CANADIAN EXHIBIT AT THE FRANCO-BRITISH EXHIBITION.

As a contrast to the mineral exhibits of the Provinces at the Canadian National Exhibition, we give herewith three views of Canadian exhibits at the Franco-British.

Plate No. 1 illustrates the Manufacturers' Exhibit. In an alcove to the left of the exit may be seen a display of coal, iron ore, etc., and steel rails from the Algoma Steel Company.

Plate No. 2 represents the agricultural section. Engines from E. Leonard & Sons and from Fairbanks, Morse & Co. are shown. Plate No. 3 shows the mineral section. Fifty-one cases, similar to those seen in the photo, were used to display these exhibits.

In the left foreground is seen a pyramid of building stones, slate, brick, cement, etc.; in the centre fore-

PLATE 3.—MINERAL SECTION.

ground a pyramid of silver-lead ores and silver-zinc ores from British Columbia.

In the central large case the Mond Nickel Company displays nickel-copper ore and products. There are also here cobalt-nickel and silver ores, mica, pyrite, and a large exhibit from the Canadian Copper Co. Apatite, corundum, talc, and asbestos are also included.

Thirty transparent photographs of mining plants embellish to crown of the large case.

QUARTZ AND FELDSPAR.

By Edson S. Bastin.

From Advance Chapter Mineral Resources of the United States.

QUARTZ.

Introduction.

Quartz, the most abundant of all minerals, occurs in a great variety of forms and is utilized commercially in many different ways. Certain transparent colored varieties, such as rose and smoky quartz and amethystine quartz, have a gem value and are discussed in the chapter on precious stones. Sand used for building, molding, and in glass and pottery manufacture, is also discussed in other parts of this volume, as are tripoli and sandstone and quartzite used for building purposes, and quartz used as an abrasive, although all these materials are nearly pure quartz. This chapter deals only with massive crystalline quartz (often called vein quartz), with flint, and with quartzite which is used for other than building or paving purposes.

Massive Crystalline Quartz.

Quartz of this variety is usually white, though occasionally rose colored or smoky. It occurs in vein or dikelike masses, unmixed with other minerals, or as a constituent of pegmatite. In the latter occurrence it is produced as an accessory in the mining of feldspar. The States now producing massive crystalline (vein) quartz in commercial quantity are Connecticut, Illinois, Maryland, New York, and Pennsylvania. Small quantities were formerly marketed from Maine, but these quarries are so far from the principal markets that the quartz can not now be sold at a profit.

Quartzite.

This rock may be described as a sandstone in which the spaces between the quartz grains have been completely or almost completely filled, either through a further deposition of quartz between the grains or through a recrystallization of the quartz of the original grains. The result is a solid mass of quartz. In Cherokee County, N.C., a hard, vitreous quartzite of Cambrian age is extensively quaried for use as a flux in copper smelting.

Flint.

The name flint is properly applied only to quartz of exceedingly compact texture, dull surface, and perfectly conchoidal, splintery fracture. It commonly occurs in the form of more or less irregular nodules in limestones. Chert is another name applied to flint occurring in this way. Flint or chert nodules occur abundantly at several localities in the United States, notably in the Cretaceous limestones of central Texas, a locality in the west portion of the city of Austin being the most accessible. So far

as known very little domestic flint has ever been commercially utilized except as road material, though its quality appears to be equal to that of the imported flint. All the true flint consumed in this country comes from France, Greenland, Norway, and England, and is imported cheaply as ballast. Many of the smaller and nearly spherical nodules are used in tube mills, but much of the material is fired in kilns and then ground for use in the pottery trade. The flints, which are usually gray to nearly black in their natural condition, become perfectly white on burning and fracture somewhat, so that grinding is facilitated.

Methods of Grinding.

In the grinding of the massive forms of quartz two general processes are used, which may be called the "wet process" and the "dry process."

In the wet process the quartz may be crushed just as it comes from the quarry, or it may first be highly heated in kilns and then fractured by turning upon it a stream of cold water. The first crushing is effected by jaw crushers or if the quartz has previously been burned it may be crushed in chaser mills. In a few mills the chasers revolve in wet pans and are periodically stopped to allow the crushed quartz to be shoveled out. After crushing, it is ground in "wet pans" provided with a pavement of flat-faced quartz or quartzite blocks over which move several large blocks of similar material, the crushed quartz being pulverized between these blocks and the pavement. The grinding in wet pans usually occupies about twenty-four hours, the load ground in a single pan varying from 1,200 to 1,800 pounds. From the wet pans the paste-like mass of quartz and water is drawn into settling troughs, the first settlings being in some cases returned to the pans for finer grinding. From the settling troughs it is shoveled out upon drying floors heated by steam or hot air or else is dried in small pans which are placed tier on tier on heated racks constructed of steam pipes. Finally the dried material is bolted to various degrees of fineness and packed in bags for shipment, or it may be shipped in bulk.

In the dry method of treatment the quartz is usually crushed first in a jaw crusher and then between steel rollers, though in some cases it goes from the jaw crushers to a gyrating crusher before passing to the rolls. Quartz to be used for filters and for abrasive purposes is then screened to various degrees of fineness, usually through revolving screens, and is packed in bags for shipment. In the manufacture of the finer grades for use in pottery, wood fillers, scouring soaps, etc., the material after leaving the roll crushers is ground in tube mills, either of the continuous or of the intermittent type. It is then graded to various sizes either by bolting or by a pneumatic process whereby the quartz powder is carried by a strong air current through a series of tubes and receptacles, the distance to which the quartz is carried being dependent on its fineness.

Uses.

Quartz of the kinds dealt with in this report is used for a great variety of purposes, the principal uses being in the manufacture of wood filler, pottery, paints, and scouring soaps. In pottery the quartz serves to diminish shrinkage in the body of the ware and is used also in many glazes. Quartz for these purposes should be nearly free from iron-bearing minerals. In general the analysis should show less than one-half of 1 per cent. of iron oxide. Finely ground quartz is used in paints in various proportions up to one-third of the total pigment used. Its chemical inertness prevents it from combining with other constituents of the paint and increases the resistance of the paint to the weather. Crystalline quartz is superior to silica sand for this purpose because the ground particles are highly angular and tend to attach themselves more firmly to the painted surfaces, thus giving the paint what is known as a "tooth" and after some wear affording a good surface for repainting. This angularity of the grains also renders the ground crystalline quartz superior to silica sand in the manufacture of wood fillers. In scouring soaps and polishers ground crystalline quartz is preferred to silica sand, not only because of its greater angularity, but because of its superior whiteness.

Massive quartz, crushed and graded to various degrees of fineness, is extensively used in the manufacture of sandpaper, sand belts, as a scouring agent with sand-blast apparatus, etc. The qualities which render it particularly serviceable for these purposes are its hardness (No. 7 in the Mohs scale), which is slightly greater than that of steel, and its conchoidal fracture, the absence of definite cleavage planes causing it to crush to fragments with sharp, angular edges and corners. For such abrasive purposes massive quartz is far superior to sand or crushed sandstone, since the grains of the latter are likely to be more or less rounded. Blocks of massive quartz and quartzite are used in the chemical industry as a filler for acid towers and to some extent as a flux in copper smelting. Much ground quartz is used in filters, and some of the most finely pulverized grades are used in tooth powders and in place of pumice as a cleaner by dentists.

Within recent years crystalline quartz and also sand has been used to some extent in the manufacture of silicon and ferrosilicon by electrolytic processes, much of the output being produced at Niagara Falls. The metal silicon, which is a crystalline metallic substance of bright silver luster, has a specific gravity of about 2.49 and a melting point of about 1,430° C. Various grades are produced, running from 90 to 98 per cent. silicon, the purity depending for the most part on the purity of the crude materials used. It can readily be cast into rods, and because of its high electrical resistance, which is about five times that of carbon, it is used in the manufacture of rheostats and electrical heaters. Silicon and ferrosilicon are extensively used as a hardener in steel manufacture and in the manufacture of alloys for copper and bronzes. Another important use of metallic silicon promises to be in the manufacture of chemical ware, its resistance to nearly all acids, combined with the fact that it can be cast in molds, making it suitable for these purposes. Chemical ware made of fused quartz has been on the market for some time, most of it being of European make. These wares are usually white and semi-transparent. They soften only about 1,400° C (2,552° F.) and show great resistance to sudden changes of temperature, the coefficient of expansion being extremely small. The principal drawback to the use of these wares, especially in quantitative chemical work, is that the somewhat rough character of their surfaces makes it difficult to wash thoroughly all material from the dishes.

Mode of Occurrence of Feldspar.

The feldspars are among the most widely distributed minerals and occur as constituents of nearly all rocks. In these occurrences, however, the feldspar is usually in too small grains and too intimately associated with other minerals to be of commercial importance. Com-

mercial feldspar usually occurs as a constituent of pegmatites. These are rocks of extreme coarseness and irregularity of texture. In mineral composition they may vary greatly, but those of present commercial importance belong chiefly to two types—(1) the granite pegmatites, which are essentially giant granites, their minerals being the same as those most abundant in ordinary granites, namely, quartz, potash-feldspar, muscovite, biotite, tourmaline, etc.; and (2) the soda pegmatites, which contain no quartz, no tourmaline, and little or no mica, but consist mainly of the soda feldspar, albite, with small quantities of hornblende. By far the larger number of the feldspar quarries of the United States are in deposits of granite pegmatite; only a few in southeastern Pennsylvania and adjacent parts of Maryland belong to the soda pegmatite type.

Pegmatites occur in or near most areas of crystalline rocks, usually as dikelike masses, following whatever planes of foliation or easy fracture may be present in the surrounding rocks, though in some cases cutting across these and often forming irregular bodies of considerable size. Different pegmatite masses even in the same region often differ considerably in coarseness, and even a single mass may vary greatly in coarseness from point to point. In general only a small part of the pegmatitic material of a region is sufficiently coarse grained or sufficiently free from iron-bearing minerals to be of commercial value. The geologic evidence generally supports the view that the pegmatite is really but one type of igneous intrusion, the molten rock magma being characterized by the presence of large quantities of gases or water vapor, which facilitated the formation of large crystals. The relative proportions and the quality of the different pegmatite constituents vary in different deposits, some being valuable chiefly for their mica, others for their quartz, and others for their feldspar. In some, two or all three of these minerals can be exploited. In a few cases the pegmatite is exploited principally for its gem minerals and its compounds of the rare metals.

The feldspar may occur as large crystals, occasionally 15 to 20 feet across, unmixed with other constituents, or they may be intergrown with quartz or with other minerals. The intergrowth with quartz is in some cases irregular, but in other cases it consists of crystals of quartz and feldspar, from several inches to several feet across, which penetrate one another in such a manner that on certain cleavage faces of the feldspar the quartz forms peculiar patterns somewhat resembling the cuneiform inscriptions on ancient monuments. To such intergrowths the name "graphic" granite has been given, from the Greek verb *graphein*, to write. Analyses of many specimens of graphic granite have shown that it is characterized by a very nearly constant proportion between the quartz and the feldspar, the feldspar forming from 70 to 80 per cent. of the rock and the quartz from 20 to 30 per cent. Two specimens of a graphic intergrowth of potash feldspar and quartz analyzed in the laboratory of the United States Geological Survey showed, respectively, 72.9 and 73.7 per cent. of feldspar, with 27.1 and 26.3 per cent. of quartz, although one specimen was approximately four times as coarse as the other. A graphic intergrowth of potash feldspar and quartz from Elfkarleo, in Sweden, which was so fine grained that the graphic structure could be seen only under the microscope, showed upon analysis about 79.2 per cent. of feldspar and 20.8 per cent. of quartz.

The finer-grained types of graphic granite are utilized commercially in some districts, as, for example, in southeastern Pennsylvania; but among many feldspar miners the opinion prevails that the finer-grained varieties contain so much quartz as to render them commercially valueless. This opinion probably has its origin in their somewhat deceptive appearance, the fineness of grain causing them to appear richer in quartz than is actually the case. From the evidence furnished by analyses it would seem clear that from the commercial standpoint at least the proportion between quartz and feldspar in graphic granites of all textures may be regarded as nearly constant, so that the finer-grained types are as valuable commercially as the coarse. Graphic textures are not observed in any of the soda pegmatites.

Methods of Mining.

The methods of feldspar mining are very simple. The excavations are nearly always open pits, usually of rather irregular form, the valueless portions of the pegmatite being avoided wherever possible in the mining work. In a few Pennsylvania quarries where the pegmatite masses are rather flat-lying and are overlain by a roof of worthless rock short tunnels have been driven from the open pits.

In Maine, Connecticut, and New York the pegmatite is usually firm and undecomposed, even in the surface outcrops, and it is necessary to sink drill holes and to blast out most of the material. In Pennsylvania and Maryland, however, the pegmatite is in most cases much decayed at the surface and the materials can frequently be excavated with the aid only of picks, shovels, and crowbars. In a few of these quarries kaolin produced by the decay of the feldspar has been found in the past in sufficient quantities to be of commercial importance, though none is now produced. This difference in the character of the pegmatite deposits in the two regions is due to the fact that the Pennsylvania-Maryland region is unglaciated, while in the more northerly region glacial ice planed off most of the products of rock decay.

In the smaller quarries where the rock is firm the drilling is usually done by hand, but in most of the larger quarries steam drills are used. The large masses are then broken with sledges into pieces about 6 inches in diameter, the more micaceous and quartzose parts and the portions carrying iron-bearing minerals being at the same time sorted out and discarded. In most of the Pennsylvania and Maryland quarries where the weathered materials near the surface can be excavated with the aid only of the pick and shovel, screening and sometimes washing is often necessary to separate the dirt from the spar. In some of the larger and deeper quarries derricks and drags are used in hoisting the spar to the surface, the material being then loaded into wagons and hauled either to the railroad for shipment or to the mills for grinding. In some quarries the wagons descend into the pit along an inclined roadway.

Commercial Availability of Deposits.

The question whether it will pay to work a given feldspar deposit depends upon a number of different factors, chief among which are (1) distance from the principal markets, (2) distance from the railroad, (3) quality and quantity of the material, (4) market conditions, and (5) ease of working. Favorable conditions with respect to some of these factors may counterbalance unfavorable conditions with respect to others. The deposits of Connecticut, New York, Pennsylvania, and Maryland are worked at a considerable advantage when compared with those of Maine, being much nearer the principal markets. Because of this advantage, hauls by team of 6 or 8 miles

from the mines to the railroad are permissible in certain of the more southerly districts, while under present conditions in Maine a deposit to be worked profitably must usually be within 3 miles of a railroad or of navigable water.

The requirements of the potter's trade demand that in general the percentage of free quartz associated with the feldspar shall not exceed 20 per cent. in the ground product, and certain potters demand a spar which is nearly pure, containing probably less than 5 per cent. of free quartz. In order to be profitably worked, in most feldspar mines between one-fourth and one-half of the total material which must be excavated should contain less than 20 per cent. of free quartz.

A factor of the utmost importance is the quantity of iron-bearing minerals, black mica, hornblende, garnet, or black tourmaline, which is present and the manner in which these minerals are associated with the feldspar. The requirements of the pottery trade demand that the spar be nearly free from these minerals, which if present produce brown discolorations in white wares. In order that a deposit may be worked profitably these minerals if present in any appreciable quantity must be so segregated in certain portions of the deposit that they can be separated from the spar without much more hand sorting and cobbing than is necessary in the separation of the highly feldspathic material from that which is highly quartzose or rich in muscovite. A number of pegmatite deposits of coarse grain are rendered worthless for pottery purposes by the abundance of one or more of these iron-bearing minerals. The presence here and there of minute flakes of white mica (muscovite) is characteristic even of the highest grades of commercial feldspar, and chemically this mineral is not injurious. It is, however, exceeedingly difficult to pulverize the thin, flexible mica plates to a fineness equal to that attained by the feldspar, and it is therefore necessary in mining to separate carefully as much of the muscovite as possible from the spar.

Methods of Grinding.

The methods used for grinding feldspar are similar in a general way in all of the Eastern States and are very simple. The soda spar quarried in southeastern Pennsylvania is first burned in kilns, which serves to fracture it and thus facilitate grinding. Most feldspar, however, is fed just as it comes from the quarry into a chaser mill consisting of two buhrstone wheels about 3 to 5 feet in diameter and from 1 to 1½ feet thick, attached to each other by a horizontal axle, as are the wheels of a cart. The horizontal axle is attached at its center to a rotating vertical shaft, which causes the buhrstone wheels to travel over a buhrstone bed, the feldspar being crushed between the wheels and the bed. In a few mills the spar before going to the chaser mills is crushed in a jaw crusher.

The material as it comes from the chasers is screened, the tailings being returned to the chaser mills for recrushing, while the fines go to tube mills for their final grinding. The tube mills consist of steel cylinders revolving on a horizontal axis. They are usually lined either with hard-wood blocks or with blocks made of natural or artificial siliceous brick, and are charged with Norway or French flint pebbles 2 to 3 inches across. Feldspar for pottery purposes is usually ground for from four to six hours, and in that time is reduced to a fineness of at least 200 mesh. Some of the poorer grades of feldspar used in glass manufacture are ground only for from two to three hours, great fineness not being required in such material. Feldspar for use in abrasive soaps is sometimes ground for as much as ten hours. The type of tube mill used by most feldspar grinders is about 6 feet in length, and it grinds from 2 to 3 tons of spar at one charging. Certain millers' however, claim to effect a considerable saving in power by the use of larger mills, which grind from 4 to 6 tons at one charge. After grinding, the spar is ready for shipment either in bulk or in bags. The red spars from Bedford, N.Y., and Bedford, Ontario, have a faint pinkish tint when ground, but the cream-colored and white spars grind to a pure white. In a few mills the ground spar is allowed to settle slowly in water, so as to separate the finer from the coarser material, but this method is now rarely employed. Two hundred mesh to the inch is the figure usually given as the fineness required by pottery manufacturers, and it is probable that most of the material placed on the market comes within this limit.

In a new mill of large capacity recently erected near Middletown, Conn., the feldspar is crushed first in a gyratory crusher and then between steel rolls. It then goes to a rotary dryer and to aerial jig screens designed to free the material from mica flakes and iron-bearing minerals. After this it is ground in continuous-feed tube mills.

Uses.

The principal consumers of feldspar are the pottery and enameled brick and electrical ware manufacturers, its main application being as a constituent part of both body and glaze in true porcelain, white ware, and vitrified sanitary ware, and as a constituent of the slip (underglaze) and glaze in so-called "porcelain" sanitary wares and enameled brick. The proportion of feldspar in the body of vitrified wares usually falls between 10 and 35 per cent., though sometimes less and sometimes more. Its melting point being lower than that of the other constituents, it serves as a flux to bind the particles together. In glazes the percentage of feldspar usually lies between 30 and 50. The trade demands that feldspar for pottery purposes be nearly free from iron-bearing minerals (biotite, garnet, horneblende, tourmaline, etc.) and contain little if any muscovite. In regard to the percentage of free quartz, the requirements vary with different potters. A few manufacturers of the finer grades of pottery demand less than 5 per cent. of free quartz, and may even grind the spar themselves so as to be sure of its quality, preferring to insure a constant product even at higher cost by themselves mixing the requisite quantity of quartz with the spar. Most potters get satisfactory results with "Standard" ground spar carrying 15 to 20 per cent. of free quartz, and in some cases the percentage runs even higher. In the finely ground mixture as it comes from the mills it is difficult to separate the quartz from the feldspar by physical methods on account of the extreme fineness of the material. Chemical analysis seems to be the readiest means of determining whether its percentage is high or low.

Feldspar is also used in emery and carborundum wheel manufacture as a flux to bind the abrading particles together.

Small quantities of feldspar are used in the manufacture of opalescent glass. The feldspar used for this purpose is ranked as No. 3 by the miners; it usually contains more free quartz and muscovite than that used for pottery purposes, and in most cases also contains fragments of iron-bearing minerals. Most of the spars known to the writer which are used for opalescent glass are notably richer in soda than in potash. They are usually ground only to a fineness of 50 to 60 mesh.

Small quantities of carefully selected pure feldspar are used in the manufacture of artificial teeth. Some is used in the manufacture of scouring soaps and window washes, the fact that feldspar is slightly softer than glass rendering these soaps less liable to scratch windows or glassware than are the soaps in which quartz is the abrasive substance. One firm in New York State crushes pegmatite for poultry grit and for a covering for concrete and tarred surfaces to give the appearance of granite.

Much interest has recently been aroused in the use of potash feldspar for fertilizing purposes. Potash is an important plant food, which, in fertilizers, has usually been applied in the form of wood ashes or of easily soluble potash salts (sulphate, carbonate, or chloride) imported from Germany. The Department of Agriculture has recently conducted preliminary experiments to determine the availability of finely ground potash feldspar as a substitute for the more soluble potash salts. The following statement is quoted from the report on these tests:

> The evidence so far obtained appears to indicate that under certain conditions and with certain crops feldspar can be made useful if it is ground sufficiently fine. On the other hand, it is highly probable that under other conditions the addition of ground feldspar to the land would be a useless waste of money. At the present stage of the investigation it would be extremely unwise for anyone to attempt to use ground rock, except on an experimental scale that would not entail great financial loss.

If further experimentation shows that ground feldspar has a wide efficiency as a fertilizer, it will undoubtedly lead to the utilization of many of the pegmatite deposits which, because of insufficient coarseness, too large a percentage of quartz, or too great an abundance of iron-bearing minerals, are not valuable as a source of pottery material. Deposits of this kind, favorably situated with respect to the railroads, are numerous, especially in the vicinity of the active feldspar quarries. An equally important result will be the utilization of much of the material which is discarded at the present feldspar quarries.

A number of processes have been patented in this country for the dissociation of potash feldspar to obtain the more readily soluble potash salts, but none of these have as yet been successfully applied on a commercial scale. What is perhaps the most promising method effects the decomposition through electrolytic methods.

EXCHANGES.

The Mining and Scientific Press—August 29, 1908.

The editor of the *Mining and Scientific Press*, Mr. T. A. Rickard, has completed a tour of inspection through the Yukon dredging region. To the current issue of the Press he contributes the first of a series of articles, in which it is his evident intention to clear away misapprehensions. Mr. Rickard's statements do not support those made in the columns of the *Engineering and Mining Journal* of New York. To some of the latter the CANADIAN MINING JOURNAL had occasion to take exception.

The Mexican Mining Journal—September, 1908.

The *Mexican Mining Journal* asserts that the outlook is favorable for satisfactory mining legislation. "It cannot be denied," remarks our bright contemporary, "that great harm has been done the country by the mere proposing of a restrictive policy on foreign very much the benefit of the new capital, both for private enterprises and to sustain the public revenues. In fact, this very need, which is becoming more evident daily, in public and private affairs, is a strong assurance that the restrictive features of the proposed law will not be enacted."

The Engineering and Mining Journal—Sept. 5, 1908.

Percy E. Barbour has an article in this number on the Goldfield Consolidated 600-ton mill. This large mill will commence treating ore during the latter part of this year. It embodies the last word in modern mill design and equipment. The ore will be crushed by stamps and tube mills, concentrated on Deister tables, and the pulp will be acynided in Pachuea agitation tanks. We can here notice but a few of the features of the plant. A Vezin N. 3 sampler, handling 2-inch material and taking a 5 per cent. or 10 per cent. cut. The mill building is entirely of steel construction. The roof and side material is asbestos-protected corrugated metal. The foundations of the mill building alone contain 7,000 cubic yards of concrete. The mortar block is entirely of concrete.

The Mining World—September 5, 1908.

Mr. Alex. Gray, late of the South African Journal, now of Montreal, writes in this number of the property and plant of the Right of Way Mine, Cobalt. The physical condition of the mine is outlined, and Superintendent Houston's methods are critically and favorably commented upon. Referring to the original agreement under which the property was acquired by its present owners, Mr. Gray remarks that, hopeless as the bargain seemed at first, "one carload extracted from a surface cutting on the Right of Way, about 500 feet from the La Rose shaft, . . . reimbursed the Ottawa promoters of the project and gave impetus to an enterprise . . . that has paid to June, 1908, 20.99 per cent in dividends.

The South African Mining Journal—August 8, 1908.

This number of our contemporary contains an editorial on "The Problem of Drill Steel." Having discussed the matter with a visiting American mining engineer, the *S. A. Mining Journal* supports his contention, that inferior drill steels are in use on the Rand. It is stated that this conclusion could have been reached independently by watching the results of the stope-drill contest. "Many thousand pounds a year" could be saved "by the use of better steel, and the improved tempering of steel." Five out of the nine machines that competed experienced trouble with their drill steels. If, under special conditions, this was the case, how much more loss and trouble must there be in working the year round?

PERSONAL AND GENERAL.

Dr. Milton L. Hersey, Montreal, has given $10,000 to endow a fellowship in the Chemistry Department of the Kingston School of Mining.

Mr. T. A. Rickard, of the Mining and Scientific Press, San Francisco, recently made a trip to the Yukon and Alaska in the interests of his journal.

President J. H. Plummer, of the Dominion Iron and Steel Company, has purchased a $50,000 mansion in Rosedale, Toronto, to which he will shortly remove.

We regret to announce the death of Mr. George G. Blackwell, the senior and founder of the firm of George G. Blackwell, Sons & Co., Limited, Liverpool, England. Mr. Blackwell's death took place at Waterloo on August 26th.

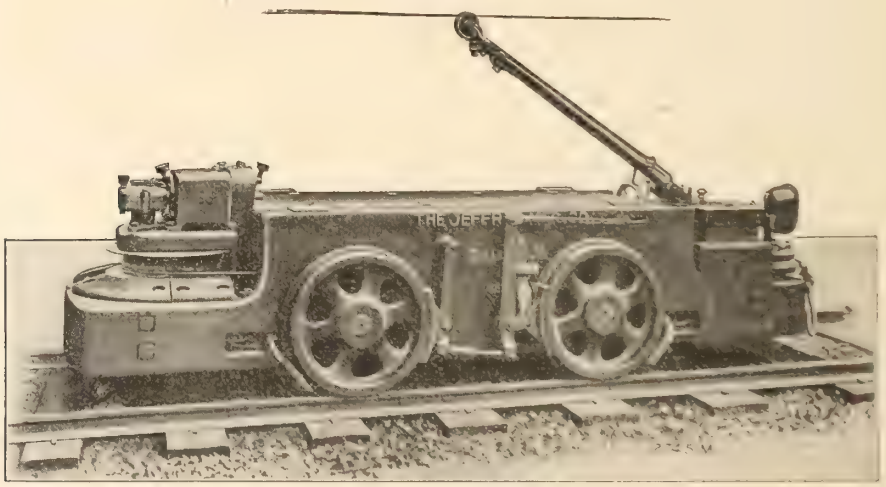
Mr. A. A. Hassan, mining engineer, has returned from a professional tour of Mexico and California. After visiting the Right of Way and Victoria mines in Cobalt, Mr. Hassan will proceed to Larder Lake, where he will examine several properties. Mr. Hassan's headquarters for the present will be the Victoria mine, Cobalt.

CORRESPONDENCE.

Editor's Note.—The following letter we are glad to reproduce. To gather the opinions of men in the field is exactly our object. So far we have received many letters, not for publication, some of which have been merely personal complaints or expressions of individual animosities. Such communications do not lend themselves to use in the CANADIAN MINING JOURNAL. Whilst it is our clear duty to help in every way to remove difficulties, only harm results from undue bitterness. But the letter printed hereunder contains a practical suggestion, and comes from a man actually in the "bush":

NEW LISKEARD, Sept. 7, 1908.

The Editor of the Canadian Mining Journal.



SIR;—I have been reading up my arrears of the MINING JOURNAL, and I find several things that as a prospector interest me. You ask the man from way-back his opinion as to "Discovery before Location." The Mines Act say (if there is no order-in-council lately changing it) that a license-holder can stake out and record three mineral claims in any mining division in Ontario, and he can also stake and record on as many licenses as other people will supply him with, and the result is that the District of Nipissing is staked out with thousands of claims that have never been prospected, and the syndicate of lawyers, doctors and storekeepers who furnished the licenses, recording fees and grub stakes are lighter in pocket and sore on the mining business, or else they form a wildcat stock company and soak their neighbors. If we are to have "Discovery before Location" there must be more prospecting and less staking.

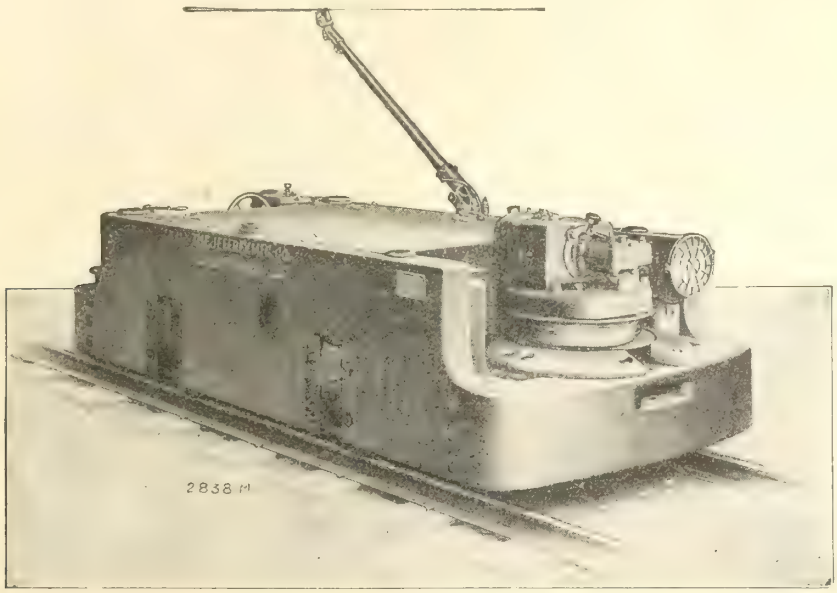
I would suggest that a license-holder be not allowed to stake on the license of anyone but himself three claims and no more, and I think you will agree with me that if a prespector gets one claim in a season that is worth developing he is doing well.

Yours truly,

License-holder 1575. THOS. S. TAYLOR.

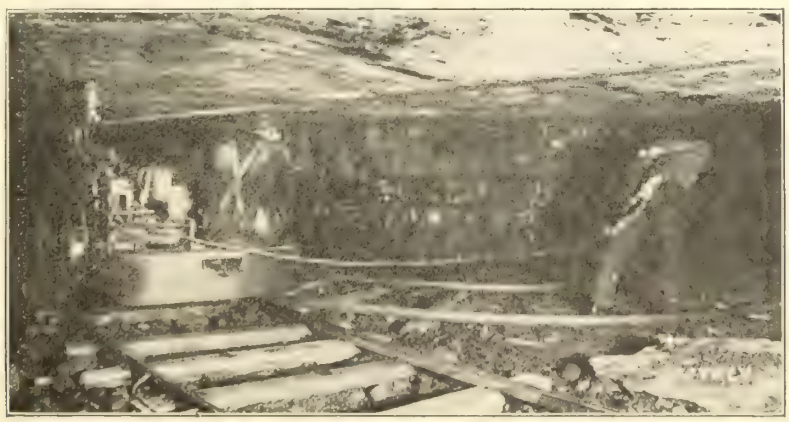
INDUSTRIAL PAGE.

THE JEFFREY CRAB LOCOMOTIVE.



The Jeffrey Manufacturing Company, of Columbus, Ohio, has recently added to its line of electric mine locomotives, a new type of gatherer, known as the Jeffrey Crab Locomotive. The gathering locomotive commonly used is provided with a reel of flexible insulated conductor, which enables it to enter the rooms for the purpose of delivering empty mine cars to the working places, and for hauling out the loaded cars. When the rooms are driven to the dip on steep grades, however, it is difficult for a locomotive which has to enter the room, to work efficiently against the grade. Again, where the tracks are practically level and the cars are not heavy, it is found economical to push the empty into the room by hand, so that mechanical means are required only for hauling out the loaded cars.

The advantages of employing, in such cases, a locomotive capable of pulling out the loaded cars without entering the rooms has prompted the Jeffrey Mfg. Co

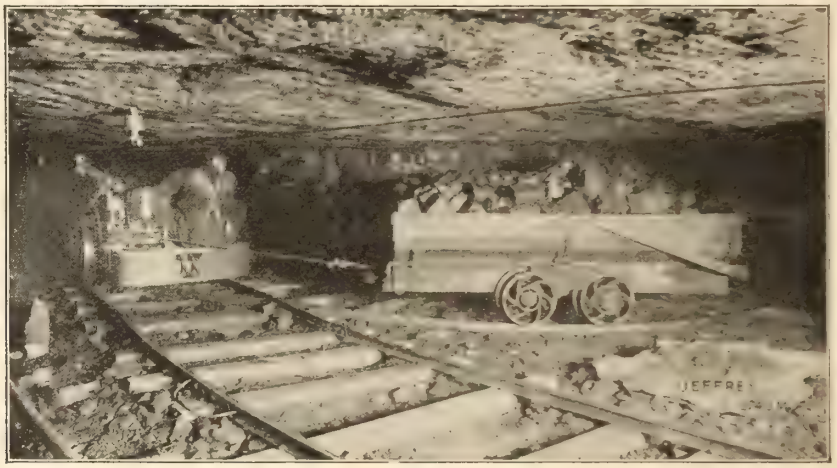


to bring out this crab locomotive, so named from a small winding drum, or crab, which is mounted on the forward end of the locomotive; 350 feet of ⅜-inch flexible wire cable wound on this crab is used for pulling the loaded cars from the rooms and out onto the entry tracks.

There are several methods of operating this locomotive to advantage, the choice depending upon the system of mining followed where the locomotive is used. With the double entry system, the locomotive usually hauls a trip of empty cars into one entry and drops them off at the rooms where they are required. Returning on the other entry, it stops in front of each room where a loaded car is ready. The trip rider then drags the cable into the room, attaches it to the car and signals the motorman, who starts the crab motor and pulls the car out to the entry track. The locomotive then either pulls it to the next room or leaves it standing until as many cars have been drawn from the rooms as are required to make up a trip. Then it pushes them together, they are coupled up, and hauled to the partings. On the return trip the entry cars are distributed in the entry from which the loads have just been removed, and the locomotive gathers the loaded cars from the entry which was supplied with empties on the preceding trip.

Where the single entry system is employed, the locomotive usually runs in with a train of empties. Stopping successively in front of the rooms in which loaded cars are ready, it hauls each car to the entry track and pushes it ahead to the next room, dropping off an empty to replace each loaded car taken out. When all empties have been distributed, it then proceeds to the parting with the loads gathered. By each of these methods a locomotive can gather from 75 to 200 cars per day, depending upon local conditions.

The crab device is made as compact as possible, to avoid crowding the rest of the locomotive equipment. It consists of a cast-iron drum, upon which a steel cable is wound. This is mounted on a vertical axis, and is contained in a frame, the top of which supports the motor, which is connected by suitable gearing and a friction clutch to the drum. The motor drives this gearing through a worm and worm-wheel, so that when it stops, the gearing is locked against further motion. The drum is driven by the gearing through a friction clutch, which acts not only as a smooth starting device for the cars, but also as a safety device in case a car becomes derailed or the motorman fails to throw off power until the car bumpers strike those of the locomotive. Without this friction arrangement the cable would, in such cases, break, or serious injury would result to the gearing or to the motor itself.



The motor that actuates the crab, being entirely

separate from the locomotive motors, is controlled by a separate starting box, and when the car approaches the entry tracks the motorman starts the locomotive ahead. As it advances past the switch points the car follows and runs out upon the entry tracks without either the locomotive or the winding of the crab being stopped.

The crab may be stopped when the car stirkes the locomotive, but the locomotive need not stop until the room is reached from which the next load is to be hauled. Then the trip rider uncouples the cable and drags it into that room for the car. The arrangement is such that the cable may be paid out from either end of the locomotive. Ordinarily, however, it is more convenient to take the cable out past the motorman, as that end of the locomotive is then opposite the room mouth, and the motorman can watch the light carried by the trip rider, and can see him signal to start winding. He can also watch the car to better advantage, as it takes the switch, and can stop instantly if it should become derailed.

One great advantage claimed for the crab locomotive is that, except where there are rooms driven to the rise at so great a pitch that the cars cannot be pushed into them by hand, it may replace animal haulage at once without making any changes in the tracks or conditions in the rooms.

When the rooms are driven to the rise and it is necessary for the locomotives to enter them in order to push the empty cars to the working places, a gathering locomotive, many types of which are made by the same company, is necessary, as ordinarily it is impracticable to use the crab device for hauling cars into rooms.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay—September 3.

The visit of the representatives of the Institution of Mining Engineers (England) who were invited over to Canada by the Canadian Mining Institute is, so far as Cape Breton is concerned, a thing of the past. The visitors were cosmopolitan, including three German gentlemen and one Belgian engineer. Scotsmen predominated largely in the British representatives, and these gentlemen were naturally quite at home in Cape Breton, which had more aptly been named "New Hebrides" than the islands to which this name has been actually given. Accompanied by a host of gentlemen more or less intimately connected with the coal trade, and by the Governor and Premier of Nova Scotia, the visitors on the 26th inspected, or rather attempted to inspect, the mines of the Dominion Coal Company. They made a hurculean attempt, visiting No. 2 Reserve, the Hub, and No. 6 Colliery, relieved by a mid-day luncheon provided by the Coal Company. It is to be feared the visitors obtained a very hazy idea of the geography of the Glace Bay neighbourhood, as they rushed all day from point to point by special trains. Some of the visitors showed great interest in the submarine workings of No. 2, particularly Herr Bergrat Goebel, a genial gentlemen from Westphalia, who found even our eight foot Phalen seam to be a tight fit for his height and girth.

On the following day the party visited the works of the Steel Co. in Sydney, which is a tidy day's work when done thoroughly. In the evening, nothing daunted by the lavish hospitality of the Steel Co. during the day, the visitors partook of a banquet given in their honour as the guests of the Canadian Mining Institute, by the Mining Society of Nova Scotia. Governor Fraser elcomed the guests of the evening, and proposed the toast of Canada, which he humourously said no man but himself was large enough to do justice to. Those who know the Nova Scotian Fraser will appreciate this remark, for in every sense of the word Governor Fraser is a big man. Speechifying went on until some time in the wee sma' hours ayont the twal, including two speeches in their own language by our visitors from the Fatherland. One gentleman from London, Eng., hoped that next time he visited Canada the "town" of Sydney would have grown into a "large city." However by two-thirty international misunderstanding was reduced to a minimum, and the general flavour of "Scotch" which had pervaded the songs and the evening generally culminated in the singing of Auld Lang Syne in the orthodox manner.

On the Thursday the Nova Scotia Steel and Coal Co. took charge of the visitors and showed them all the wonders of Sydney Mines and its environs. The guests were each presented with a small and tasteful brochure containing a concise and well written account of coal mining at Sydney Mines from

the beginning on. Rumour has it that this brochure was not even written in manuscript a week previous to the visit of the British party. If so it is but another sample of the way they hustle on the other side of the water when occasion calls. Sydney Mines from its old associations with old country men and methods through the General Mining Association possesses more than ordinary interest to such a party as have recently honoured us with their presence, and the distribution of the little pamphlet referred to was no doubt appreciated as it surely deserved to be. Next day, declining the pressing invitation of the President of the Nova Scotia Steel Co. to visit Wabana, the visitors left for the West, and for rest we hope.

The visit of such an assemblage of mining men from across the water will be likely to prove of far greater value to industrial Canada than cart-loads of prospectuses and flotations on the London market. "When," to use the words of Governor Fraser, "these gentlemen have seen the sun arise out of his cold bath in the waters of the North Atlantic, and have followed his course past the Great Lakes, across the prairies, through the foothills, and over the Rockies, until they have seen him set in the warmer waters of the Pacific," they will understand somewhat of Canada's prospects, and of its mineral wealth, and they will go home to tell the news with the sure confidence of men who have seen what they are talking about. That is if they survive the trip across! It is no light task that these gentlemen have undertaken, and it is to be hoped that they will not be rushed around in quite such a breathless fashion for the rest of their journey as was the case in Cape Breton.

The "Times" has recently published a series of articles on "Industrial Canada" by Dr. A. Shadwell, and in the issue of August 15th Nova Scotia was dealt with. It is rather interesting at times to see ourselves "as others see us," and Dr. Shadwell's article is on the whole a fair and appreciative one. All the same it must be disconcerting to Haligonians to know that their city wears "a shabby, decayed, dead-alive air," and that Halifax "has not stirred for fifty years." In the portion that refers to Sydney, it is stated that this city is in the centre of the chief coal mines in the Dominion, "which is singularly poor in this most important source of wealth." Dr. Shadwell says that "there is, for all practical purposes, no coal between the Atlantic seaboard and the Rocky Mountains." We think this is not exactly true, but it is sufficiently true to accentuate the importance of our Cape Breton coal fields to the Dominion at large. Referring to the dispute between the Coal and Steel Companies, Dr. Shadwell makes some pertinent comments on American mehtods of finance, and refers to "a gentleman from Boston, of the name of Whitney, who seems to be a born promoter of the true adventurous type," the lagacy of whose financial enterprise Dr. Shadwell thinks affords "an instructive object lesson in the difference between American and British methods of promoting industries." If by "British" is meant Canadian methods we are inclined to agre with the writer in the "Times," and that this is the writer's intention is evidenced by his contrasting the works of the Nova Scotia Steel Co. and their development with the works and rise of the Dominion Iron & Steel Co., which latter Company our writer evidently thinks was originally handicapped by the mistakes of its American promoters, to whose door he lays three errors—first, too lavish capital expenditure, second, the launching of so huge a concern in pure anticipation of business to come, and third, incompetent management. Dr. Shadwell writes "In Canada they have a way, which does more credit to their courage than to their prudence, of taking hold of enterprises without any proper training or experience. They stick to it, learn from their own mistakes, and pull through; but it is very costly." Well, we have the consolation that Dame Experience charges high fees for her schooling, but then the instruction is very thorough. After devoting about two columns to Sydney, our writer dismisses Glace Bay in about a dozen lines as " a mining settlement, situated in a singular region," and tells of a party of Yorkshiremen who came, "took one look, and the next train back." We remember those same Yorkshiremen. Their fares out had been paid by the Coal Company, and this was their idea of honesty. We may further remark that there are a good many Yorkshiremen around the same singular region, who not only remained themselves, but sent for their families, their brothers' families, their mothers and fathers, and the third and fourth generation. The particular sort of Yorkshireman Dr. Shadwell has heard of is one that we can spare at any and at all times.

However it may hurt the civic pride of Sydney Mines and Glace Bay to contemplate the fact, we think Dr. Shadwell is right in regarding Sydney as the natural metropolis of Cape Breton. Its central position and its magnificent harbour mark it out for this destiny. Dr. Shadwell rather unnecessarily says that Sydney is "a long way from everywhere, and on the road to nowhere, except Newfoundland." We have an idea that Sydney is on the road to a good many places, and that it will not long remain under the stigma of being unknown in the old country, where Dr. Shadwell says the name is "usually associated with Australia."

The conclusion of the "Times" article is more to the point. It is as follows: "Nova Scotia, with its valuable mines, its admirable harbours, and the marked industrial capacity of its people, canot fail to carry its already considerable manufacturing interests into a very important position in the economic development of Canada."

Sydney—August 26.

Early this morning, August 26, the European and American delegates, along with the representatives of the Canadian Mining Institute, arrived in Sydney. Last evening a large body of members and ojcials of the Mining Society of Nova Scotia, together with Lieut.-Governor Fraser, Premier Murray, and other Government officials, had gathered to welcome the visitors, who, throughout their journeyings in Nova Scotia, are to be the guests of the above mentioned Society.

At 9.30 this morning the whole gathering left on a special Sydney and Louisburg train for Glace Bay. Here they were taken in hand by the Dominion Coal Company, represented by President Ross, General Manager Duggan, Sales-Agent Alex. Dick, and others. A luncheon was given at the Technical School building. The excursionists returned to Sydney at 5 p.m.

A smoker was tendered the visitors at the Sydney Hotel at 8 o'clock this evening. Addresses of welcome were read by Lieut.-Governor Fraser, and by Mr. C. J. Coll, President of the Nova Scotia Mining Society.

To-morrow, August 27, the visitors will be the guests of the Dominion Iron and Steel Company, who will also be their host at a luncheon.

Sydney—August 27.

The banquet tendered this evening by the Mining Society of Nova Scotia in honour of the Canadian Mining Institute and their British and foreign guests was eminently successful. At 9.15 p.m. the banquet commenced. Covers were laid for 175 guests, and the menu was a practically good one

Mr. C. J. Coll, President of the Mining Society of Nova Scotia, occupied the chair. He was supported on his right by Lieut.-Governor D. C. Fraser and upon his left by Premier Murray.

Shortly after eleven o'clock the toast list commenced. "The King" was hailed with loud acclaim.

"The German Emperor" was proposed by A. C. Ross, M.P., and responded to by Dr. Kraynik and Herr Bergrat Goebel.

President Coll proposed the toast of "Canada" and Lieut.-Governor Fraser responded becomingly, expressing the sincere hope that this visit would result in the encouragement and further development of Canada's great mineral industries.

Proposing the toast of "Sister Societies," Premier Murray touched upon the mutual benefits to be received from such excursions of distinguished industrial authorities as the gentlemen who were now visiting Canada.

Mr. Hugh F. Marriott responded for the Institute of Mining and Metallurgy; Mr. Walter Johnson for the Iron and Steel Institute. Mr. James Barrowman, on behalf of the Institute of Mining Engineers, made grateful allusion to the "superabundant hospitality" extended to him and his companions. Responding on behalf of the South of Wales Institute, Mr. W. J. Rees predicted that in a hundred years Great Britain would be importing her coal supplies from Canada. He alluded in appreciative terms to the plant and product of the Dominion Iron and Steel Company.

Dr. Herman Wupperman, representing foreign sister societies, spoke in German. He congratulated Canadians upon possessing in such abundance those natural resources that are in such world-wide demand.

Dr. William Campbell spoke for the American Institute of Mining Engineers.

Dr. W. G. Miller, President of the Canadian Mining Institute, paid a warm tribute to the hospitality extended to the excursionists by Quebec and Nova Scotia. Other speakers were Dr. Frank Adams, Mr. R. E. Harris, Professor F. H. Sexton, and Mr. Alex. Dick.

Last night, August 26, the visitors were given a luncheon by the Dominion Iron and Steel Company. They leave to-morrow morning for Sydney Mines, where they will be the guests of the Nova Scotia Steel and Coal Company.

Sydney—August 28.

The visiting mining men spent the last day of their stay in Cape Breton in visiting the plant of the Nova Scotia Steel and Coal Company at Sydney Mines and in enjoying the hospitality of that Company and of President James Ross of the Dominion Coal Company. The party, numbering in all about 80 persons, left here for North Sydney at 9 a.m., where they took special cars for Sydney Mines. There they were taken in charge by President R. E. Harris, General Manager Thomas Cantley, and Superintendent John Johnston.

Returning at noon to North Sydney, they were entertained at luncheon by the N. S. Steel and Coal Company in the rooms of the Eastern Club.

Lieutenant-Governor Fraser, Mr. James Ross, Premier Murray and other prominent citizens were present.

Later the visitors were taken on Mr. Ross's yacht "Shiela" to Mr. J. K. L. Ross's residence, where a garden party was given in their honour.

They leave for Quebec to-morrow morning.

ONTARIO.

Cobalt—September 5.

The Miller Lake (20 miles west of Elk Lake City) discoveries are most encouraging. The Miller Lake Syndicate claims show a number of healthy veins. Smaltite and niccolite are the chief vein constituents. The chief need of the district, after further prospecting, is the making of good roads. Prospecting will be carried on by several groups until snow interferes. After this attention will be directed to underground work. Small shipments of picked ore will be made as soon as the rivers and lakes are frozen. Silver is reported on one of the claims of the Moore-Logan syndicate. The three Gates claims are being actively opened.

A purse of three hundred and fifty dollars has been subscribed for prizes for the drilling contest on Labour Day, September 7. The first prize will be $200, the second $100, and the third $50. Diabase, not granite, will be the rock drilled this time.

Cobalt.

Hargreaves.—The litigation which has prevented the development of the Hargreaves lot which adjoins the Kerr Lake Mine on the south has been settled. The Government is to receive a royalty of 25% and costs of litigation. The title to the property is put in E. R. C. Clarkson's name. This property is very favorably situated and should prove valuable.

Silver Bar.—Work on this property, which adjoins the Savage on the south, has been suspended. The prospects seem to warrant the expenditure of a considerable sum of money in development work, as the physical condition of the property is excellent. The discovery of a very rich vein on the Savage and the locating of a strong vein of cobalt in shaft No. 2 on the Silver Bar indicate that further prospecting will develop a paying mine.

City of Cobalt.—Five cars of ore, a total of 127 tons, were shipped during the first week of September. One car of high grade ore went to Copper Cliff and three cars of low grade and one of medium grade to the American Smelting and Refining Co. at Denver, Col. The mine is in first class shape. At the 200 foot level work is being pushed on a 10 in. vein of high grade ore. Power has been obtained to date from the Cleveland Cobalt, but at the last meeting of the directors it was decided to purchase a 12 drill Sullivan Compressor. 13,157 shares of Treasury stock have been issued to shareholders at $1.00 per share.

Chambers-Ferland.—The first shipment made, consisting of 30 tons of high grade ore, went to Denver, Col., on September 2. Drifting has been started in both directions in shaft No. 1. A cross cut has been started at 80 feet in shaft No. 2. On September 5 a new vein was located in the northern part of the property from which a number of silver nuggets have been taken.

Trethewey.—Last month a dividend of five per cent. was declared. The statement made by the Directors of the financial position of the Company was as follows:

"Sept. 1, cash in bank, $123,543.96; due from smelters, $41,794.94; ore sacked and in transit, $23,112.79; a total of $188,451.69. The dividend takes $47,272.50, leaving a balance of $141,179.19.

The financial statement, August 31, 1907, showed cash in bank of $56,903.86, and ore on hand and in transit of $23,353.40. The net earnings of the Company have been at the rate of over 23% on the total issued capital of the Company. The physical condition of the mine has been greatly improved by recent development work."

The Company's financial year will be made to correspond with the calendar year. The annual meeting will be held in January.

The improvement in general conditions and the very encouraging development in the Cobalt District have resulted in the resumption of work on many properties in the outlying districts and a material increase in the working forces on many "prospect properties."

A force of men has been at work for some weeks trenching on the Cullen Cobalt property in Lot 1, Con. 12, Lorrain.

Several good calcite veins have been located on the Ritchie claim in Lot 2, Con. 12. A shaft has been sunk 20 feet on a calcite and quartz vein with niccolite and smaltite.

At the Big Fissure Mine, in Lot 3, Con. 11, Lorrain, work is being pushed on shafts No. 1 and No. 2. 35 men are employed.

A small compressor, boiler and hoist have been ordered by the St. Lawrence Cobalt Company and will be installed on the property on the south shore of Sasaginaga Lake.

Montreal River.—The past month has seen a very noteworthy improvement in the new camps in this District. The most important of which is the development of a rich vein of shipping ore on the Motherlode Mine, in James Township. This property was purchased this spring from Herbert Gates by a syndicate represented by W. R. Mowery. Mr. Gates had located a vein of decomposed calcite from which he took several hundred pounds of nuggets of very pure silver. A test pit sunk on the vein showed six to eight inches of vein matter but very small values. When the property passed to Mr. Mowery, it was decided to develop it by driving a tunnel in from the side of a hill with the expectation of cutting this vein at a depth of 80 feet. 36 feet from the mouth of the tunnel a cross vein was encountered and this was followed to the main vein. At the junction a vein of calcite, smaltite and silver, assaying from two to six thousand ounces was cut and a drift of 120 feet on the vein shows from 4 to 6 inches of shipping ore which for 25% of this distance will assay two to three thousand ounces. This is specially important, as many surface showings in this district are very similar to the original Gates discovery.

Cragg Claims.—These claims, which comprise 1,156 acres, are located in a narrow tongue of a diabase which extends from the Montreal River through Con. 6 in James and 1 and 2 in Smythe. They are controlled by Shirley Cragg, who is one of the pioneers of the Montreal River District. Six of the claims are passed, four on native silver discovery and two on cobalt with small silver values. On the S. W. ¼, N. ½, Lot 7, Con. 1, Smyth, three important veins have been located. Vein 1 has been uncovered for over 300 feet. The vein matter is calcite, decomposed on the surface, in which nuggets of native silver are found in a black muck. At a depth of 1 or 2 feet the calcite carries high silver values. The mineralisation and width of the vein are both irregular, running from one to six inches in width and from small values to 5,000 oz. in silver. On the S. W. ¼, N. ½, Lot 3, Con. 6, James, a vein has been uncovered for 400 feet on the contact between the diabase and conglomerate. The vein matter is calcite, from one to twenty inches wide, with occasional enrichment of cobalt and native silver. A shaft has been sunk on this vein. A comprehensive plan of development has been made and is being carried out under the direction of Mr. Cragg and Morgan C. Milne, his superintendent.

Gow Ganda Lake.—The latest discovery in the Montreal River District is near Gow Ganda Lake, four miles west of Miller Lake, between Miller Lake and the east branch of Montreal River. Rich ore has been sacked and brought into town.

BRITISH COLUMBIA.

Rossland.

Mr. W. Y. Williams, consulting engineer for the Granby Co., was in the city a few days ago looking over the work that has been done on the California-Giant since his last regular inspection. Development work has been in progress in the depths of this property for over a year, and the work is rapidly approaching a point where the sought-for ore body should be encountered. Mr. Williams, who is well-known by all the old-timers throughout this district, having for years been connected with the Granby mines at Phoenix, also has charge of the development work being done on the Independence group in the Similkameen, the Holden group in the State of Washington, and other promising properties. The Indepedence group is under bond to the Granby Co. for $100,000. Mr. Williams states that the work on the California-Giant is progressing in a satisfactory manner, and that good results are being obtained.

The Hattie Brown mine in the South Belt has been leased by two Rossland miners, and a good body of ore has been opened up during the preliminary work. The shaft on the Golden Rule is now down over thirty feet. The St. Elmo has joined the shipping list, having sent a car of picked ore to the smelter.

The big mines are maintaining a good average output for the present condition of the metal market. Shipments will be augmented as soon as copper reaches a normal figure. The ore shipments continue to run over 5,000 tons per week, the Centre Star shipping over 3,000 tons of this.

The following lead receipts at the Trail smelter (for the month of July) give a good idea of the amount of lead ore the different mines of the district are shipping to Trail and the proportion of lead in the ore of each mine:

Mine.	Net. weight. Pounds.	Lead contents. Pounds.
Arlington	228,204	5,975
Alpha	39,939	15,650
Blue Bird	29,106	1,863
Blue Bell	809,294	489,722
Curlew	13,479	566
Empress	2,138	17
Ferguson	170,015	47,260
Giant-Golden	35,564	24,118
Keystone	15,283	397
Little Robert	1,040	172
No. 1	27,432	823
Reco	81,162	33,982
North Star	1,408,949	290,298

Westmount	86,758	6,770
	9,480,798	4,422,732

Boundary.

Ore shipments from the big copper producers of this district fell off to a considerable extent during the last couple of weeks of August. This was owing to the uncertainty of the coke supply. For the week ending September 6th the Granby shipped but 13,741 tons, the B. C. Copper Co. maintained about its average, 13,483 tons; the Snowshoe sent out 1,270 tons, and 60 tons came in from the Mountain Rose, making 28,554 tons for the week, and a total shipment from the Boundary District this year to that date of 881,378 tons.

It will be noted that the Snowshoe is now shipping ore to the Consolidated smelter at Trail, having sent out over 400 tons per day for three days of the week. Only a small amount of Snowshoe ore is to be shipped, while the price of copper remains as low as it is at present. This ore will be sent to the Trail smelter for fluxing purposes. Extensive development work is now in progress, and will be maintained on both the War Eagle and Snowshoe holdings of the Consolidated in Phoenix camp, and ore will be blocked out preparatory to heavy shipments the moment the condition of the metal markets warrants such action.

Seven of the furnaces at the Granby smelter are now in full blast, a fairly steady supply of coke being available from the Michel coke ovens, where the shipping facilities have been put in working condition again after the fire. No coke is coming in from Fernie yet, but it is expected that shipments will be

made from that point in the next week or ten days. Granby ore shipments will, no doubt, be up to their average during the present week. The furnace now cold at the Granby smelter is being enlarged. It will be made 4 ft. 4 in. longer than at present, or 22 feet in length, and it will take about three weeks to complete the job. All of the furnaces will be changed over in this way, and it will be well on into February of next year before the work can be completed, as they can only work on one furnace at a time.

The Granby directors in convention at Boston took no action upon the dividend question. It is stated that the dividend paid three months ago was not designated as "quarterly," and that a division of profits at this time was not necessarily due. While local stockholders, naturally, feel a little disappointed, still they recognize that action of this kind is to be expected immediately after a crisis such as has just been passed.

Mining operations have been resumed at the Brooklyn and Rawhide mines of the Dominion Copper Co. after a shut-down of several weeks. The big furnace at the Boundary Falls smelter will be blown in shortly as some coke is beginning to arrive on the ground. No shipments to the smelter were made by the Copper Co. last week, but their mines will, no doubt, show up on the shipping list during the current week.

The B. C. Copper Co. was affected but little by the big Fernie fire, as their supply of coke is obtained from the International Company at Coleman. They have maintained steady, average shipments while the Dominion Copper Co. was closed down, and the Granby Co. mines did not work Saturdays or Sundays lately.

Hon. Wm. Templeman, Minister of Mines, and W. R. Brock visited the mines of the Boundary during the past week.

G. P. Jones, superintendent of the Nickle Plate, Hedley, has secured an option on the Golden Zone for around $65,000. The Golden Zone is a promising mine and the 5-stamp mill recently erected is now giving satisfactory results.

The Apex, which the B. C. Copper had a bond on a short while ago, had now been bonded to W. D. McMillan. There is a good body of ore on the Apex. Development work is to be continued on the Fortune. The extensive gypsum deposit near Spence's Bridge is to be opened up in the near future. Operations will be begun shortly.

Charles Camsell, Dominion Geologist, has been looking over the platium bearing zone of the Upper Tulameen River. Topographical work is now being done in this district by the survey. As soon as proper transportation facilities are built into this district it will make a name for itself with its rich mineral deposits.

Nelson.

Ore shipments from this district for the past week amounted to 1,545 tons, making 61,585 tons for the year to date. Good results are being gained at the Blue Bell. A recently shipped car of ore returned over $600. A test car of Hewitt ore has been put through the zinc separating plant of the Kootenay Ore Co.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney, Sept. 9.—At 2 p.m. to-day fire was discovered in the extreme southern part of Section 5 of No. 1 Colliery of the Nova Scotia Steel and Coal Company. It was found impossible to approach within 100 yards of the fire. The section is filled with smoke and is being flooded. Flooding will take 48 hours. Work will be delayed for less than a week. It is thought that the fire is due to carelessness on the part of miners.

ONTARIO.

Sault Ste. Marie, Sept. 9.—The plant of the Algoma Steel Company will be re-opened on Sept. 15. Rush orders from the Transcontinental Railway are reported.

Cobalt, September 4.—The Temiskaming, in sinking a new shaft, supposed to be away from the ore bodies, where it could be used for the main shaft, struck a rich blind vein at a depth of 75 feet, of calcite, niccolite and native silver.

Port Arthur.—Fine specimens of ore showing chalcopyrite, hornite and visible gold have been brought into town lately from Sturgeon Lake district.

A winding-up order in the matter of the Atikokan Iron Company, Limited, of Port Arthur, has been granted at Osgoode Hall, and John Dix Fraser, manager, of Port Arthur, was appointed provisional liquidator.

The petitioners were Mackenzie, Mann and Co., Limited, creditors, for moneys advanced, to the amount of $2,523.

The Canadian Fairbanks Co., Ltd., got judgment some time ago for $1,241, and $38 costs. The sheriff made a seizure on August 28, and a sheriff's sale was advertised to take place on Sept. 10. According to the petitioners, the Atikokan is unable to pay its debts.

The Atikokan Iron Company, Ltd., was incorporated on April 14, 1905, "for carrying on the business of a mining, milling, reduction, and development company." The capital stock was $1,000,000, divided into 10,000 shares at $100 a share. "All subscribed, and fully paid," reads the petition.

Directors from Toronto were D. D. Mann, vice-president; William Mackenzie, and Z. A. Lash.

BRITISH COLUMBIA.

Fernie, Sept. 4.—Great progress is visible on the reconstruction of Fernie. Bricks are being made from a local deposit of clay, recently discovered, by the Fernie Brick Company. All buildings are to be fireproof, and a more beautiful city will arise on the site of the old. Brick and stone are used in the business buildings, and concrete for many residences.

Nelson.—The Silver King mine resumed shipments of ore to the Consolidated smelter at Trail on August 27 after some months of idleness.

During the fortnight ending August 22 there were upwards of 39 mineral locations recorded in districts centreing in Nelson. This is a cheerful indication of the general activity.

A rich find of gold is reported from the Granite-Poorman mine. Mr. J. Laing Stocks brought some specimens into Nelson on the 12th of August.

The mining industry has almost completely recovered from the temporary effects of the recent Fernie fire. While there has been a marked falling off of ore outputs and the Dominion Copper Company has temporarily shut down, an immediate recovery is certain.

Fernie, Aug. 26.—The corrected list of fire losses that are covered by insurance shows a total of $1,448,000. The largest

loss will be suffered by Lloyds, $235,000. The Phoenix Company of London comes next with $136,000.

Kaslo.—The Hon. Wm. Templeman, Minister of Mines, and Mr. R. W. Brock, Acting-Director of the Geological Survey, were informally entertained by a committee of business men on Monday evening, August 24.

Grand Forks, Sept. 1.—Plentiful supplies of coke have arrived and six of the Granby Company's furnaces are now in commission. The seventh and eigth will be started shortly.

Rossland.—A fifteen-stamp mill is to be erected at the Jewel mine on the Boundary.

Victoria.—There are now at the wharf bunkers of the Ikeda Mining Company more than one thousand tons of copper-gold ore awaiting shipment to the Ladysmith smelter. Monthly shipments at this rate are now possible from the Ikeda mines.

The B. C. Provincial Government has appropriated $35,000 for public improvement purposes in the re-building of Fernie.

YUKON.

Dawson.—The miners of Black Hills Creek are to have a road constructed. The local administration has made an appropriation and work already is well advanced.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The Institute of Metals, founded June 10th, is established on a firm basis with Sir Wm. White as president and an influential council. Its membership includes representatives of the leading firms interested in the British metal trade, in addition to many prominent foreigners, and it is expected that when the first general meeting is held in November the number of members will have reached 500.

Valuable experiments are being carried out by the Mining Association of Great Britain at Altofts, in accordance with a recommendation of the Royal Commission on Mines, to ascertain the causes of dust explosions and the best means of preventing them. Some important results have been already obtained, showing the most promising preventive to be stone dust.

SPAIN.

A Parisian company has undertaken the working of the grey copper and argentiferous mines of Calcena, known for some centuries past, which have from time to time been extensively operated. An electric plant will be installed.

BELGIUM.

Prof. Nuel states that there are 17,000 miners in Belgium afflicted with nystagmus—an involuntary laberal oscillatory movement of the eyes said to be caused by working in a dim light. The remedy is the employment of improved lamps in place of the candle.

RUSSIA.

A number of English capitalists and Transvaal gold miners have gone to Eastern Siberia for the purpose of acquiring gold-bearing areas. A staff of mining engineers is included in the party.

A new branch of the Siberian Railway is projected from Irkutsk northwards into the gold-producing regions of Vitirusk and Olekminsk.

The Russian Dnieprovskiy Metallurgie Co. has contracted to supply 360,000 poods, or 5,806 tons, of steel rails to the Papanese government for the southern sections of the Manchurian Railway.

SOUTH AFRICA.

Efforts to locate the extensions of the famous Johannesburg vein or Main Reef series have met with but slight success. On the western end the series runs into the great Witpoortje Break, and the continuity of formation ceases, though auriferous patches may be found, and towards the east the series becomes spotted in value with stretches of barren ground interspersed.

The Zaaiplaats State mine experiment in the Transvaal has failed. The government attempted to solve the unemployed problem by finding the men with work in the tin fields, but the results were not satisfactory, and the government sustained a net loss of £4,000.

An eight hours bill, providing that eight hours shall be the maximum length of a work day and punishing all violations with fines or imprisonment for both employer and workman, has been introduced into the Transvaal Legislature. It applies to nearly all forms of industry, and is strongly opposed by the mining interests.

UNITED STATES.

Messrs. J. V. Thompson and I. W. Semans, of Uniontown, Pa., have sold 5,288 acres of coal land in Green County in that State to a syndicate who are organizing the Emerald Coal Co., the price being reported at $1,463,000. Plans for mine development and the construction of coke ovens are under way.

The mining town of Chisholm, Minn., of about 4,000 inhabitants, on the Mesaba iron range, was destroyed by bush fires on the 5th inst. The Pillsbury and Nartley mines of the U. S. Steel Corporation, six miles west of Hibbing, in the same neighborhood, were devastated.

A new and rich gold field, 37 miles from Cripple Creek, Colorado, and about 1½ miles west of the copper belt, is being developed. A rush of prospectors has set in and all available ground is being staked.

A strike of the union coal miners of Wyoming involving 10,000 men began on the 1st inst. owing to the reduction of wages by the Mine Owners' Association.

About 30 coal miners were suffocated in Hailey-Ola coal mine No. 1, near Haileyville, Oklahoma, on August 26th, when fire destroyed the hoisting and air shafts, cutting off air from the mine.

AUSTRALASIA.

The gold yield of Victoria for 1907 amounted to 695,576 oz. fine, valued at £2,954,617. This is a decrease of 76,714 oz. as compared with the previous year's output, which is accounted for by several of the lode mines working out, the closing of some of the deep lead mines and the lack of new discoveries.

Good reports are received from nearly all the Tasmanian

tin mines, recent rainfalls having furnished an ample supply of water.

CHINA.

A company has been formed at Shanghai, China, with $20,000,000 capital to take over the Hauyang iron and steel mines and the Ping Hsing collieries. One-third of the amount has been already subscribed.

MEXICO.

The Kansas-Cananea Copper Co., capitalized at $10,000,000, has been organized by a merger of the Mexican holdings of the Silver Mining Co., Cons. Gold and Copper Co. and the Miller Mining Co. The properties included are 1,350 acres in extent.

The burning oil well of S. Pearson & Sons, near Tampico, has been extinguished after some 3,000,000 barrels of oil had been destroyed.

STATISTICS AND RETURNS.

OUTPUT FOR AUGUST, DOMINION COAL CO.

	Tons.
1	42,985
2	58,156
3	25,739
4	36,197
5	40,308
6	18,825
7	18,113
8	20,754
9	39,997
10	15,462
	306,536
1st January to 31st August, 1907	2,296,269
1st January to 31st August, 1908	2,609,488
Gain over 1907	313,219

The August shipments from the Dominion Steel Company's plant broke all previous records in the history of the company. The details of the company's output (not shipments) for the month are:

	Tons.
Pig iron	21,000
Ingots	26,511
Steel rails	15,246
Wire rods	5,070

It is expected that a showing equally good will be made in September as the company has plenty of orders on the books.

North Sydney, N.S., Sept. 2.—The output of coal at the mines of the Nova Scotia Steel & Coal Company for the month of August exceeded that of the previous month by about 400 tons. The figures would have gone over 60,800 had not a break occurred in the working days caused by the men observing the annual P. W. A. day. On that day the mines were closed.

Following are the figures for the different collieries:

No. 1	19,344
No. 2	4,010
No. 3	23,359
No. 4	1,444
No. 5	9,731
Total	58,068

Coke blast furnace and open hearth are running full force. Prospects for the company's continued prosperity were never brighter than at the present time. The hearth resumed operations a few days ago and the first output from that department came out on Monday.

The output of the Crow's Nest Pass Coal Company for the week ending August 28 was 19,847 tons, a daily average of 3,308 tons. For the corresponding week of 1907 the figures were respectively 22,132 tons and 3,688 tons.

The output of the Crow's Nest Pass collieries for the week ending September 4th was 20,108 tons, a daily average of 3,351 tons.

COBALT ORE SHIPMENTS.

Cobalt ore shipments were rather light last week, totalling 1,018,000 lbs., or 509 tons, against 711 tons the previous week. Only eight mines shipped, the La Rose being the biggest shipper of the lot.

Total shipments for the year to date are 26,850,949 lbs., or 13,425 tons. Shipments for the week and year to date are:—

	Week ending Aug. 29	Since Jan. 1.
Buffalo	91,000	850,950
Kerr Lake	61,000	583,794
La Rose	414,000	4,758,612
McKinley	61,000	2,206,040
Nova Scotia	40,000	351,775
O'Brien	141,000	4,437,627
Townsite	40,000	211,700
Temiskaming & H. B.	120,000	1,108,500

A new shipper appears in the list of mines shipping from Cobalt Camp last week, the Chambers-Ferland property joining the shipping list with a shipment of 61,650.

Nine mines shipped 1,304,460 pounds, or 652 tons. The total shipments for the year to date are 28,155,408, or 14,077 tons. Shipments for the week and year to date are:—

	Week ending Sept. 5,	Since Jan. 1.
Buffalo	[illegible]	850,950

Total	1,826	55,079

The total selter receipts for the week were 35,852 tons, and for the year to date 1,118,056.

Kaffir houses in London estimate the current month's gold production in the Transvaal at 600,000 ounces. This would be a new high record, comparing with 584,455 ounces officially reported for July, which was itself a new record, and with 355,037 ounces in August, 1907.

Value of the August output, calculated on the basis of the above estimate, compares as follows:—

August, 1908	*$12,600,000	August, 1907	11,560,000
July, 1908	12,413,000	August, 1906	10,812,915
June, 1908	12,211,000	August, 1905	9,102,485
May, 1908	12,360,000	August, 1904	6,634,340
April, 1908	11,924,000	August, 1903	5,775,195
March, 1908	12,210,000	August, 1902	3,456,610

* Estimated.

COMPANY NOTES.

The Dominion Coal Co. declared the regular quarterly dividend of 1 per cent. on the common stock. It is payable October 1 to shareholders of record on September 18.

The Right of Way, which pays its fourth dividend this month, will have disbursed $140,000 to its stockholders. The price paid originally for the property was $50,000.

The regular quarterly 3 per cent. dividend has been declared on Temiskaming stock, payable October 1, to holders of record Sep-

tember 15. Owing to an error, this dividend was yesterday credited to the Tretheway company.

The directors of the Trethewey-Cobalt mine, in sending out dividend cheques for the 5 per cent. dividend recently declared, enclosed a brief statement, giving the financial position of the company at the 1st of September as follows:—

Cash on hand, $123,543.96; due from smelter, $41,794.94; ore sacked and in transit, $23,112.79; a total of $188,451.69.

The dividend takes $47,272.50, leaving a balance of $141,179.19.

The financial statement on August 31, 1907, showed cash in bank of $56,903.86, and ore on hand and in transit of $23,358.40.

The directors say: "During the past few month, notwithstanding the low price of silver, the net earnings of the company have been at the rate of over 23 per cent. per annum on the total paid-up capital."

La Rose Consolidated has issued a preliminary statement of production and earnings for the month of August, 1908:

	Tons.	Contents.	Net. value.
Shipments	645	278,570	$123,356
On hand August 31	40	78,000	40,050
Production	685	356,570	$163,406
Less on hand July 31	57.94	79,739	38,803
August production	627,06	*276,831	$124,603
Estimated expenses			16,000
Net profit for August			$108,603

*Ounces.

The La Rose Mines, Limited, reports the following preliminary statement of production and earnings for the months of June and July:—

June production—	Tons.	Contents. Ounces.	Net. value.
Shipments	178.7485	116,088	$55,600
On hand June 30th	41.991	77,711	38,267
Production	220.7395	193,799	$39,867
Estimated expenses			$11,000
Net profit for June			$82,867
July production—			
Shipments	507.110	305,459	$140,793
On hand July 31st	57.940	79,739	38,803
Production	565.050	385,198	$179,596
Less on hand June 30th	41.991	77,711	38,267
July production	523.059	307,478	$141,329
Estimated expenses			$14,000
Net profits for July			127,329
Total for June and July.	743.7985	501,286	*210,196

*Net profit.

The Kerr Lake Mining Co. has declared a regular quarterly dividend of 3 per cent., payable September 19. Books close September 14, and reopen September 21.

The annual report of the American Smelting and Refining Company for the year ended April 30 shows that 7 per cent. was eanred on the common stock. This covers the period during which the dividend was reduced from 8 to 4 per cent.

With the payment of a dividend of $5 just declared and calling for $500,000, the Calumet and Hecla Mining Company will have distributed to its stockholders a total of $107,350,000 since is organization. Three and six months ago the disbursement was $5. In the quarter before that it was $10, and a year ago $15.

Amatite ROOFING

This advertisement will bring to your attention the best and cheapest ready roofing on the market. Here is how we prove it the best.

In the first place Amatite is made in one standard thickness, whereas other ready roofings range from a thin, flimsy half-ply to a three-ply thickness.

Right here is the point. Amatite is better made, has better water-proofing material, and weighs more per square foot than the three-ply grade of other makes, and COSTS MUCH LESS.

But in addition to its superiority in material and manufacture, Amatite has one distinction which makes it stand out above all others. IT HAS A REAL MINERAL SURFACE.

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather, the great durability.

The mineral surface is embedded in a layer of Pitch. THE GREATEST KNOWN WATERPROOFING MATERIAL Beneath this in turn are two layers of the best grade of wool felt—cemented together by more Pitch, making the whole a roofing that is ABSOLUTELY WATERPROOF.

No other ready roofing can compare with this mineral-surfaced water-proof, weather-proof, durable roof. That's why we say—DON'T BUY YOUR ROOFING UNTIL YOU HAVE SEEN AMATITE.

Free Sample and Booklet

Send for Free Booklet and Sample to-day. It will pay you to get acquainted with Amatite. Address nearest office.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries

BRITISH COLUMBIA

The Mineral Province of Canada

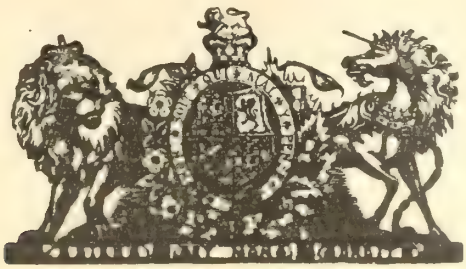
has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.



Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

THE AMERICAN TUNNEL RECORD

During January, 1908, the No 1, or River Portal Heading of the Gunnison Irrigation Tunnel, in Montrose County, Colorado, was advanced 440 feet, through hard granite rock. This constitutes the best performance in tunnel-driving on record in the United States.

The tunnel is 12x10 feet in cross section, and when completed, will be the longest artificial underground waterway in the world (30,582 feet).

SULLIVAN ROCK DRILLS size "UD" (3 in.) were the machines used by the Government engineers in making this record. Sullivan Drills have been used exclusively on this tunnel, since March, 1906.

GOOD HUNTING

The finest hunting grounds in Canada—for big game and small game, are reached by the Canadian Pacific Railway. Amongst the best must be reckoned the country adjacent to the recently opened Toronto-Sudbury line—alive with moose, deer, bear and every variety of game. This will be the first Fall this country has been accessible by rail. Go up while the hunting is at its best.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

WRITE US FOR DESCRIPTIVE PAMPHLET.
FORWARD SAMPLE OF YOUR ORE FOR PRELIMINARY TEST.

WAY'S POCKET SMELTER

For Testing Ores.

With Way's Pocket Smelter you can tell quickly, in your office or in the field, at a cost of 5c. for each test, whether ore carries gold, silver, copper or other metals of commercial value—and these tests can be depended upon. Mining Experts and Engineers say that "Way's way is the better way."

The complete outfit—with supplies for making 30 tests—can be carried without inconvenience. By the way—let us send you a copy of "Way's" Booklet—"The Prospector's Friend."

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLAR

Provincial Geologist of Ontario, formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

FIRE FIGHTING IN COAL MINES.

The first important call upon the Draeger equipment at the Dominion Coal Company's Rescue Station came on September 10th. A fire in one of the collieries of the Nova Scotia Steel and Coal Company threatened to do great damage. Unprotected miners found it impossible to get within fighting distance of the trouble. A call sent to the Dominion Coal Company met with a prompt response. Instructor James McMahon was despatched with 22 trained men from Dominion collieries 2, 9, 1, 3 and 5. Under singularly adverse circumstances the men, with the aid of the Draeger equipment, fought the fire at close quarters. The heat was so intense that it was possible for each relay to work only ten minutes at a time. Had the call come sooner, or had the Nova Scotia Company possessed an equipment of their own, flooding need not have been resorted to.

We have given a prominent place to Mr. Gray's article on the above-mentioned occurrence, especially because he emphasizes the national character of rescue and fire-fighting work in mines. The nations are awakening to a live sense of their duty in the conservation of natural resources. One most lamentable source of waste and loss is the colliery fire. The only practical safeguard is a well-trained corps of men, properly equipped with modern respiratory apparatus.

LARDER LAKE.

We are glad to present in this issue a short note on Larder Lake from Mr. H. L. Kerr. Our readers will observe that Mr. Kerr writes in a hopeful strain. In effect he states that from his personal examination of the district, there is justification for prospecting and exploratory development. Beyond this we think no competent mining man will go. It is true that striking gold specimens have been found. But the relatively small amount of sinking, drifting or tunnelling performed leaves the camp still to be classed as problematical. High purchase prices and capitalizations running into the millions have been and are the worst drawbacks from which Larder Lake can suffer. When a few payable ore shoots have been delimited and their value ascertained, there will be something to work on. Meanwhile good roads, fewer newspaper puffs, honest work and less talk are needed.

PARIS GREEN.

Out of 72 samples of Paris green examined in the year 1895, five were declared doubtful and 15 were found to be unmistakeably adulterated. Of late years, doubtless on account of the fact that the Dominion

Government investigated and reported upon the purity of the articles put upon the market, a great improvement has been observed. During the current year 150 samples, taken at random from retailers all over the Dominion, were subjected to analysis. Only one adulterated lot was found. The manufacturer of this lot was, we regret to say, a prominent Canadian concern. The sample showed incomplete solubility in ammonia. Adulterants were found in large amounts. Barytes, which would lend weight to the article, was present to the extent of 26.87 per cent., and acetic anhydride to 6.75 per cent. The pure samples were completely soluble in ammonia, and contained from 31 to 33.5 per cent. cupric oxide, and from 51.5 to 59 per cent. arsenious acid.

These figures are worth noting. Arsenic, which soon will become a staple metallurgical product in Canada, is the principal constituent of Paris green, and Paris green is itself an important article of commerce. We notice the names of four foreign manufacturers in the Bulletin issued by the laboratory of the Inland Revenue Department. It should be easily possible for Canadian manufacturers to meet the whole domestic demand.

DISCOVERY AND LOCATION.

The recent pronouncement of a United States authority to the effect that rigid requirements as to valuable discovery before location of claims would kill prospecting, has much to support it.

That discovery of valuable mineral in place is not an essential of legitimate location is tacitly acknowledged in all foreign mining countries. When the law demands such discovery, its requirements are either ignored or interpreted leniently. In several of the mining States local statutes allow a fixed period of time for marking the location after discovery. In the absence of statutory regulations it is usually understood that the prospector has a reasonable time in which to mark his location.

The tendency of mining legislation in this respect in the United States and elsewhere is strongly in favor of the man who is doing the work. Thus a prospector who has sunk a shaft, but who has made no discovery, is protected until he has made discovery. Upon discovery of valuable mineral he is allowed to make location relating back to the time of beginning work.

In this manner development is not hindered, nor false swearing encouraged.

CHINA'S NEEDS.

Reports from Shanghai indicate that China is soon to purchase large quantities of silver and copper. The Imperial Government is delaying purchase until the appearance of the report of an Imperial Commission appointed to reorganize and consolidate the Chinese coinage system. The design of both silver and copper coins is to be changed, the weights are to be increased and standardized, and the issue largely increased. The Imperial Government, after taking over all the provincial mints, will operate the plants at full capacity for some time.

There is now a pronounced scarcity of silver and copper coins throughout the vast and populous empire. An adequate expansion of currency will mean unusual demands upon the American metal producers. There is, then, sound cause for expecting a rise in the price of both silver and copper.

BREATHING APPARATUS.

The wisdom of providing collieries with breathing apparatus was illustrated lately in Nova Scotia. One section of a colliery operated by the Nova Scotia Steel and Coal Company took fire through the carelessness of employees. It was at first thought that flooding would have to be resorted to. But the Dominion Coal Company generously volunteered the services of men trained in the use of the Draeger apparatus. Equipped with these respiratory devices, the rescue party fought and conquered the fire at close range.

This is but one instance of the "insurance" value of modern breathing devices. Fires that, if left to run their course, would cause immense loss, can be coped with successfully by men instructed in the use of breathing helmets. For life-saving, after explosions, they are an absolute necessity. Their introduction into every coal mining district should be made compulsory.

ABITIBI LAKE DISTRICT.

Lying between the 48th and 49th parallels, the district surrounding Lake Abitibi is popularly supposed to be a barren, rocky, semi-arctic wilderness. Professor M. B. Baker, who has spent a few summers in the Abitibi country, contributes a letter to this issue of the Canadian Mining Journal. The statement that tomatoes can be grown and ripened so far north would be received with incredulity were the evidence not unimpeachable. This is but one item. Professor Baker's letter will be read with deep interest. He emphasizes the agricultural value of this section of New Ontario.

EDITORIAL NOTES.

We would especially draw attention to Mr. T. A. Rickard's able article on "Dredging in the Yukon," which appears elsewhere in this issue. Mr. Rickard is a mining engineer of the highest standing. He is editor of the Mining and Scientific Press of San Francisco, and he went to the Yukon this summer to study mining conditions there at first hand. In our issue of the 15th of January last, we had occasion to point out the inaccuracies of some statements made by a contributor to the Engineering and Mining Journal, with the deliber-

ate intention of belittling the mining, and especially the dregding enterprises that are being energetically undertaken in the Canadian Yukon. Mr. Rickard's article brings out the truth and justice of our contention that the mining engineers at work in the far north are proving that with a reasonable amount of time to work in, and abundance of water, the warmth of summer will extract the frost from the ground, and consequently that the frozen gold-bearing gravel can be dredged at a splendid profit.

As is explained in a letter from a correspondent in this issue, the name of an important producing gold mine was inadverently omitted from the list of Nova Scotia mines published by us on September 1st. Oldham has been one of the richest gold producers of the province. The omission was, therefore, a serious one.

The article on Mining in Western Australia should be read by Canadians. It shows what effective administration and sane methods can do. The records of dividends paid is astonishing. Canada should take the lesson to heart. We need less promoting and far more clean development.

With a few notes on the reception of the Canadian Mining Institute at Cobalt, we reproduce the scheme of Mr. A. A. Cole's mineral collection. Mr. Cole should have the gratitude of the community for his enterprise and energy. If these collections could be duplicated and placed within the reach of prospectors and others, we are sure that a large demand would be created.

The annual report of the Consolidated Mining and Smelting Company of Canada, excerpts from which appear on another page, announces that the gross value of metals produced at the company's smelting works up to date is over $31,000,000. During the year ending June 30, 1908, the gross value of metals produced was $5,428,501, as compared to $3,786,196, the production for 1907, being an increase of over 43 per cent.

THE USE OF OXYGEN BREATHING APPARATUS AT THE SYDNEY MINES FIRE.

By F. W. Gray.

A fire which occurred at Sydney No. 1 mine, of the Nova Scotia Steel & Coal Co. on the 9th September, has served to demonstrate the usefulness of oxygen breathing apparatus for underground fire fighting, and to bear out the statements put forward in a note by the writer, which appeared in the Canadian Mining Journal of 1st May last regarding lessons to be learnt from the fire at Hamstead, Eng.

The fire at Sydney mines originated some time towards the evening of the 9th inst. from a blown out shot. The seat of the fire was a partly driven room, set in some thirty feet from the back deep, at a point near to the barrier and distant about 2 1-4 miles from the shaft. The water supply was inadequate and subject to interruptions, being carried for the last 500 feet in ordinary firemen's hose, which burst under the great head of water. Owing to this the fire gained on the workmen, and involved the back deep and the room opposite to the one where it started. The fumes from the fire prevented a sufficiently close approach to make the hose stream effective in extinguishing the flames, and two men were rendered insensible by the "fire-stink." It was decided to ask the assistance of the Draeger equipment of the Dominion Coal Co. to enable the fire to be fought at closer range. A telephone message was received at Glace Bay about 8 p.m. on the 10th, and by 11 p.m. a party of twenty-four was got together, consisting of District Superintendent N. McKenzie; the instructor at the Rescue Station James McMahon, and twenty-two men from colleries Nos. 2, 9, 1, 3 and 5. Reaching Sydney at 12 p.m. they were taken by a special tugboat and arrived at Sydney No. 1 about 1 a.m. The face was reached about 3 a.m. and by 5 a.m. the fire was attacked. It was found possible to get within 50 feet of the fire in good ventilation, and a base was established at this point. The men attacked the fire in relays of three at a time, while others were detailed to brattice and timber as required. The whole of the operations were directed by Mr. McKenzie. The chief obstacle to the fighting of the fire was a heavy fall at the entrance to the second room into which the fire had spread from its original starting point on the other side of the back deep. It was found necessary to surmount this fall to get the hose on to the fire, and the heat was intense. The men could not endure it for longer than ten minutes, after which they had to retreat. The instructor would then relieve the retiring men of their apparatus and fit out a fresh relay, and so on. After working in this way from 5 a.m. till about 3 p.m. the fire was driven back and confined to the small room where it had originated. When this was done the Glace Bay men withdrew, and a dam was constructed by the workmen of the Nova Scotia Co. across the mouth of this room, and it was slowly flooded through a pipe left in the dam.

The work performed by the Glace Bay men was done under the most arduous conditions. The stream of water was so feeble owing to the breaks that it was necessary to get quite close to the flames to effect any good, and the interruptions to the water supply sometimes allowed the flames to recover the ground they had lost through the previous exertions of the workers. The heat was very great, and the steam scalded the men, until they obtained the protection of oilskins.

Some idea of the heat may be gathered from the statement of the instructor that the metal parts of the apparatus burnt his hands when taking it from the backs of the retiring relays. All the work of course was done in an atmosphere that would have been very quickly fatal to any unprotected person. The men worked by the light of electric hand lamps of the Hubbell type. Neither the weight of the lamps nor the apparatus seems to have caused the men particular discomfort. The protection afforded to the face and head by the helmets seems to have been of great value. One of the men wore a mouth breathing apparatus, as owing to his large physique no helmet had been found large enough to fit him. He suffered from the heat and steam on his face, and could not advance as far as those fitted with helmets, although he is an old fire-fighter. It is evident that for smoke and fire the helmet type is likely to be the most useful one.

The lessons of this fire are exactly those of the Hamstead fire, which we may quote in part from the article of 1st May, above referred to.

"1. To be really effective and useful in time of need, oxygen apparatus should be kept on the spot, and should be available for use instantly."

Had the Draeger apparatus been used at Sydney Mines when the fire was first noticed it could of course have been extinguished with much greater ease than was actually the case.

"2. It is absolutely necessary that men be trained in the use of these apparatus in conditions that are as nearly as possible actual conditions, that is, in really unbreathable gases. . . . Untrained men are worse than useless when the emergency comes. No man knows his hidden idiosyncracy until he makes the test."

In the case under review, there can be little doubt that the effective way in which the men from Glace Bay dealt with the fire and handled their apparatus was due to their having trained rigidly and conscientiously in the smoke chamber. Every man was known to be fit for the work.

3. . . . Relays of fresh men should be ready to take up the work."

Twenty-four men were in the Sydney Mines party, as compared with the small parties at Hamstead. They were able to work in relays and constantly relieve each other. Of course it must be admitted the conditions were distinctly different from those prevailing at Hamstead, for in that case the whole mine was involved.

"4. An adequate supply of oxygen and cartridges should be at hand."

The Glace Bay corps took with them ten apparatus, with sufficient spare oxygen cylinders, potash cartridges, and electric lamps to last each apparatus for twelve hours.

A further lesson, which although it may not meet with general approval, we consider cannot be too strongly emphasized, is the national character of rescue work in mines. The conditions which existed at Sydney Mines to occasion the visit of the Glace Bay corps did not fortunately involve any especial danger to human life. But there is a danger that where men have trained and lives are in danger the services of the trained men will be called upon. In our note of the 1st May we said: "We know that willing volunteers will never be wanting when other men's lives are in danger, and it is hard to refuse aid under such circumstances. But what right has anybody to expect volunteers from another district to risk their lives in the unknown workings of a strange colliery at long distances from their base of supplies? Such men are like the mariner in uncharted seas, and could be accused neither of cowardice nor inhumanity if under such circumstances they refused to endanger their lives. But we know they would not refuse, and therefore the national character of the matter becomes at once apparent."

That large corporations should equip their mines with such apparatus is a wise precaution on their part, and a cheap fire insurance premium, apart altogether from the humanitarian aspect. The coalfields of Nova Scotia are the property of the Government. Anything that will or may save human life is a matter for Government action. Therefore apart from anything that that the coal operators may do on their own initiative, we cannot see how either the provincial or the federal government can ignore their share of the cost and responsibility of this matter.

ANTIMONY.

Although a falling market throughout the year gave little encouragement to the development of American production of antimony, the output in the United States in 1907 showed an increase of 256 tons in quantity and of $19,497 in value as compared with the output of the preceding year, the total being 2,022 short tons, valued at $622,046, in 1907, as against 1,766 short tons, valued at $602,549, in 1906.

As usual the greater part of the antimony produced in the United States was that contained in antimonial lead and sold by the smelters in that form. As this alloy is extensively used in type metal, babbitt metal, coffin trimmings, and similar wares the two metals need not be separated.

The imports of antimony in 1907, in the form of metal, regulus, ore, and salts, exceeded even those of 1906, up to that time the greatest recorded, rising in value from $1,616,381 in the earlier to $1,686,802 in the later year.

The consumption of antimony and antimony salts in 1907, as shown by the addition of the values of production and of imports, amounted to $2,308,848.

A statistical report on the condition of this industry in the United States, prepared by Frank L. Hess, has just been published by the United States Geological Survey as an advance chapter from "Mineral Resources of the United States, Calendar Year 1907." Copies of this report may be obtained by applying to the Director of the Survey at Washington, D.C.

The death rate per thousand employees occupied in coal mining in the United States reached the startling figure of 4.86 in 1907. This is an increase of 1.55 over 1906, when the rate was 3.31. The number of tons of coal mined in 1907 for each life lost was 145,471 tons, as compared with 19,950 in 1906. West Virginia coal mines showed the highest death rate in 1907, 12.35 per thousand, and the lowest production of coal per life lost, 65,969 tons. Missouri's rate was the lowest, being 0.95 per thousand men employed, and 499,742 tons of coal mined for each life lost in spite of the general impression that the mine explosions are responsible for the majority of deaths in coal mining, it is found that while 947 deaths and 343 injuries ware due in 1907 to gas and dust explosions, yet 1,122 deaths and 2,141 injuries were caused in the same period by falls of roof or coal; and 855 deaths and 2,416 injuries were ascribed to other causes.

LARDER LAKE.

H. L. Kerr.

Although the optimistic hopes of some of the early prospectors in the Larder Lake country have fallen far short of realization, yet work done there recently has disclosed the fact that several promising bodies of gold-bearing quartz exist. Whether these locations shall develop into mines remains for the future to show. That there are ore bodies sufficiently rich to warrant the expenditure of money, in order to prove their value is readily admitted by those who take the trouble to visit the camp. It must be said that a great deal of the early work done by some of the companies was sadly misapplied, and that most of the booming of the camp in the beginning was most reprehensible. Still, it would be a great pity if the foolish talk of three thousand ounce ore in the early days, causes us to overlook the possibilities of large bodies of low-grade ore, which in all probability exist.

View of Larder Lake from Harris-Maxwell.

Both at the Maxwell-Harris, in the neighborhood of Larder City, and at least two other properties seven or eight miles distant, many fine specimens of visible gold have been found, and the hope is entertained that, associated with these rich spots are large quantities of low-grade milling ore. Work is progressing slowly at both ends of the lake with the object of proving this. One small stamp mill is already in operation, and two companies have ten stamp mills nearly complete. In

Vein from which rich specimens have been taken. This and all such veins require proving and development.

each case provision has been made for the addition of more stamps and in the meantime prospecting on the possible ore bodies is being pushed ahead.

It is possible now to reach the lake from Toronto in less than twenty-four hours. A year ago the journey took the best part of a week. The Pullman train leaving the Union Station at nine o'clock every night, goes as far north as Englehart, about twenty-five miles north of New Liskeard, which station is reached about nine o'clock in the morning. From here another train may be taken three days in the week, Monday, Wednesday and Friday to Dane (formerly known as Boston), where the stage for Larder City meets every train. (Return ticket to Dane, including Pullman both ways, is $21.00). The wagon road from Dane to Larder City which has been built by the Government, is in first-class condition for probably fourteen of the eighteen miles and the balance of it is being rapidly rounded into shape. The stages run are very comfortable and considering the locality the charge of two dollars and a half each way is not at all excessive. Larder City is usually reached before dark. Good meals and sleeping accommodation may be obtained at two or three places in the city. The city consists of less than twenty buildings with a stationary population of about fifty. A small steamer belonging to the Northern Ontario Navigation Co., makes two trips daily up the lake, making it very easy for one to visit any claims in which they may be interested. If one is not interested in mining he will find it a delightful spot to spend a holiday. Not only is there good fishing in the lake but moose are plentiful not far back.

The trip may be made to the camp about four hundred and fifty miles north of Toronto, all the important locations visited and perhaps a moose got on the side, all within a week.

Wendigo Wagon Road a Year Ago.

THE LAW CASE.

Many of our readers are interested in knowing how the prosecution of that enterprising quondam barber, Frank Law, is progressing.

The move on the part of Law's counsel to render proceedings abortive by claiming that Law had won immunity by giving evidence to the Crown, was met by Assistant Crown-Attorney W. H. Price in a sur-

prisingly frank letter, published in the Toronto Telegram. It may be explained that the case is now in the hands of the County Crown-Attorney, Mr. H. L. Drayton. Newspaper reports reflected upon Mr. Price, who conducted the prosecution up to the point where it was turned over to Mr. Drayton.

We publish herewith Mr. Price's open letter to Mr. Drayton. Mr. Price's letter states the case to our entire satisfaction. If there has been carelessness, indifference, or collusion, if the ends of justice are to be defeated, if a most unmistakable crook is to be allowed to escape without punishment, it is clear that the blame will lie on some person other than Mr. Price. The following is reprinted from the Telegram of September 17, 1908: "The following letter from W. H. Price, the commissioner who took the evidence in the Russell extradition case, to Crown-Attorney Drayton sets forth the facts in connection with the Law case in a new light. Mr. Price strongly urges the point that nothing has been done by the Crown in using evidence given by Law which should prevent his being prosecuted, notwithstanding the remarks of Judge Winchester.

Rex vs. Law.

Dear Sir,—I am handing you a memorandum of what took place before Mr. Law was examined on the extradition proceedings taken by the crown in Rex vs. Russell. You will see by this memorandum the position of affairs at that time. After this, Mr. Law left the room, and was away for about half an hour, while I proceeded with other witnesses who were on hand. He then came back, and after being told that he could either give evidence or not as he desired, he submitted himself to be sworn. I beg to draw your attention to the following facts in connection with this matter:

Consulted Mr. Cartwright.

1. When Law volunteered to give any evidence which would assist in bringing back Russell, I communicated with Mr. Cartwright, the Deputy Attorney-General, and discussed the matter fully with him. He was of the opinion that evidence given in the Russell extradition proceedings, as Mr. Law had requested, would not affect or interfere in any way with the case then pending against him in the sessions.

2. That Provincial Detective Rogers discussed the matter with Mr. Law, in my presence, and saw Deputy Attorney-General and had instructions from the deputy attorney-general to take that evidence on the extradition proceedings. Law not only at this time volunteered to give evidence, but offered to pay expense of extradition proceedings.

Law was Warned.

3. Law was told, as also was his counsel, Mr. O'Connor, that he could give evidence or not as he pleased; that it made no difference to the Crown.

4. That Mr. Law's evidence taken on the extradition proceedings against Russell could not in any shape or form be given as evidence against him. In fact there is nothing in this evidence which points against Mr. Law, neither was there any attempt to glean any information from him.

KERR'S LANDING—A TYPICAL LARDER LAKE CAMP.

5. That although Mr. Law's evidence on the Russell extradition proceedings was taken on the 28th of February, 1908, and two Sessions have passed, no objection had been raised by Mr. Law or his counsel, on the score that he had given evidence in the extradition proceedings.

Fully Aware of Proceedings.

6. That you were fully aware of what had been done in the Russell extradition proceedings some months ago, and discussed it with Mr. Corley, Mr. Rogers, and other parties.

7. That Mr. Blackstock notified you on Thursday, the 10th inst., that he would make this motion, yet I was not apprised of the fact until you had reached court, and apparently discussed the matter on Monday, the 14th.

The Usual Result.

8. That Mr. Blackstock, counsel for the prisoner, did not state in court that any arrangement had been arrived at with Law, but merely stated that he was used as a Crown witness, and the usual result should follow.

9. That the Judge's statement before hearing what you had to say was not fair to the Crown or to anyone connected with the case.

Plenty of Evidence.

In addition to these points, I draw your attention to the fact that we could not in any event succeed against Law, on the charge upon which extradition proceedings were taken against Russell. The charge of conspiracy to defraud must, as a necessity, cover almost all transactions of the firm of Law & Co., Limited. I do not consider, however, as a point of law or practice, that Blackstock has raised any point that cannot be met satisfactorily, I am quite satisfied that there is abundant evidence which points to Law personally, and which should leave no possible doubt as to his conviction.

Those Present.

The parties present at the time this evidence was taken were Magistrate Kingsford, Mr. Rogers, Mr. Angus, Mr. O'Connor and myself. I do not ask you to take what I have to say in the matter, but you can consult with any of them and verify all the material outlined in this letter. It seems to me that the position taken by the court on such flimsy statements and without hearing everything that could throw light on the case was entirely uncalled for and unjustified. There is nothing to prevent this case being called and disposed of at the earliest available opportunity. You may show this letter to Judge Winchester if you so desire.

Yours truly,

(Signed) WILLIAM H. PRICE.

Onus on Crown Attorney.

P.S.—The onus in this case is surely on the defence to show any arrangement, and the duty of yourself as Crown Prosecutor not to permit anyone to impugn the motives of the Attorney-General's Department or Crown counsel.

(Signed) W. H. P.

WESTERN AUSTRALIA.

Report of the Department of Mines for the Year 1907.

In mineral production Western Australia ranks second among the states of the great Commonwealth of Australia. During 1907 Western Australia's output represented a value of £7,640,153, of which £7,210,747 was credited to gold. In respect of the production of this precious metal Western Australia is far in the lead of any of its sister states. Its closest competitor is Victoria, with a gold output of £2,954,617. In total mineral production, however, New South Wales has a strong lead. The record of this state for 1907 was £10,577,378, of which £2,922,419 is attributable to coal and £3,658,632 to silver-lead ore.

Thus Western Australia, although it produces respectable quantities of copper, lead, tin and coal, is pre-eminently a gold-producing state. Its mining laws have, therefore, been evolved, interpreted and administered more particularly from the viewpoint of the gold industry. Gold mining languishes in Canada to-day. Defective legislation and the apathy of those in authority are not the least causes of this. It is possible that some valuable lesson may be learned from a survey of Western Australia's work.

Regarding the gold production of the several states of Australia, the Territory of Papua and the Dominion of New Zealand as a whole, Western Australia's share is 46.29 per cent.

For three years, however, Western Australia's output of gold has been falling, not seriously, but quite perceptibly. The Government is adopting strong measures to check this decline. As a consequence new regions are being opened and the tide is turning. In another section of this paper we shall notice the policy of the Department of Mines of Western Australia. Meanwhile the state's gold industry claims our attention.

From the illuminating character of the statistical tables that form part of the Annual Report is is evident that close and constant attention is paid to every phase of the mining industry. Table 5 gives us an analytical view of the production of ore and gold per man employed. The maximum tonnage per man employed underground and per man above and under ground is credited to the Peak Hill gold field, respectively 821.03 tons and 410.52 tons, with corresponding production of gold per man of 127.61 ounces and 63.81 ounces. The general average value of gold produced per man employed above and under ground was £438 in 1908, and £438.32 in 1907. The average tonnage of ore raised has increased from 173.31 tons in 1906 to 187.32 tons in 1907. The number of producing mines in 1907 was 1,062, a decrease of 89 as compared with the returns for 1906.

Up to the end of 1907 the enormous sum of £17,476,578 had been paid in dividends by Western Australian gold mining companies. During 1907 dividends to the amount of £1,738,163 were distributed. There are nine companies whose nominal capital exceeds £200,000 ($1,000,000). Eight of these companies have made dividend payments amounting to sums greater than their nominal capital, and in some instances have returned 400 to 600 per cent on the original stock. One company, the Great Boulder Proprietary Goud Mines, Ltd., operating in East Coolgardie gold field, and capitalized at £175,000 (shares 2 shillings par), paid £262,500 in dividends during 1907, and has paid to date a grand total of £2,644,300. This quite takes one's breath away.

Acreage.

Under ,507 mining leases are held 61,677 acres, of which gold mining leases account for 27,587 acres. Liberal conditions for prospecting have incited a large increase in prospecting areas. Classified and tabulated lists of all these holdings in each and every gold field are given.

Men Employed.

During the past year 16,058 men were employed in "reef" or "lode" mining on the gold fields; in alluvial

mining, 1,318; making a total of 17,926. It is significant that at the mines the number of employees above ground almost equalled the number under ground. The figures are 7,113 above and 8,945 below.

Accidents.

Forty-one deaths and 374 injuries is the record for 1907 in the gold mines. The first figures give a death rate of 2.55 per 1,000 persons employed for these mines. Eight deaths resulted from accidents above ground and 33 from accidents under ground, The fatal accidents (including four deaths in mines other than gold mines) are thus classified:—

	Deaths in 1907.
Explosions	3
Falls of ground	22
In shafts	8
Miscellaneous underground	4
Surface	8
	45

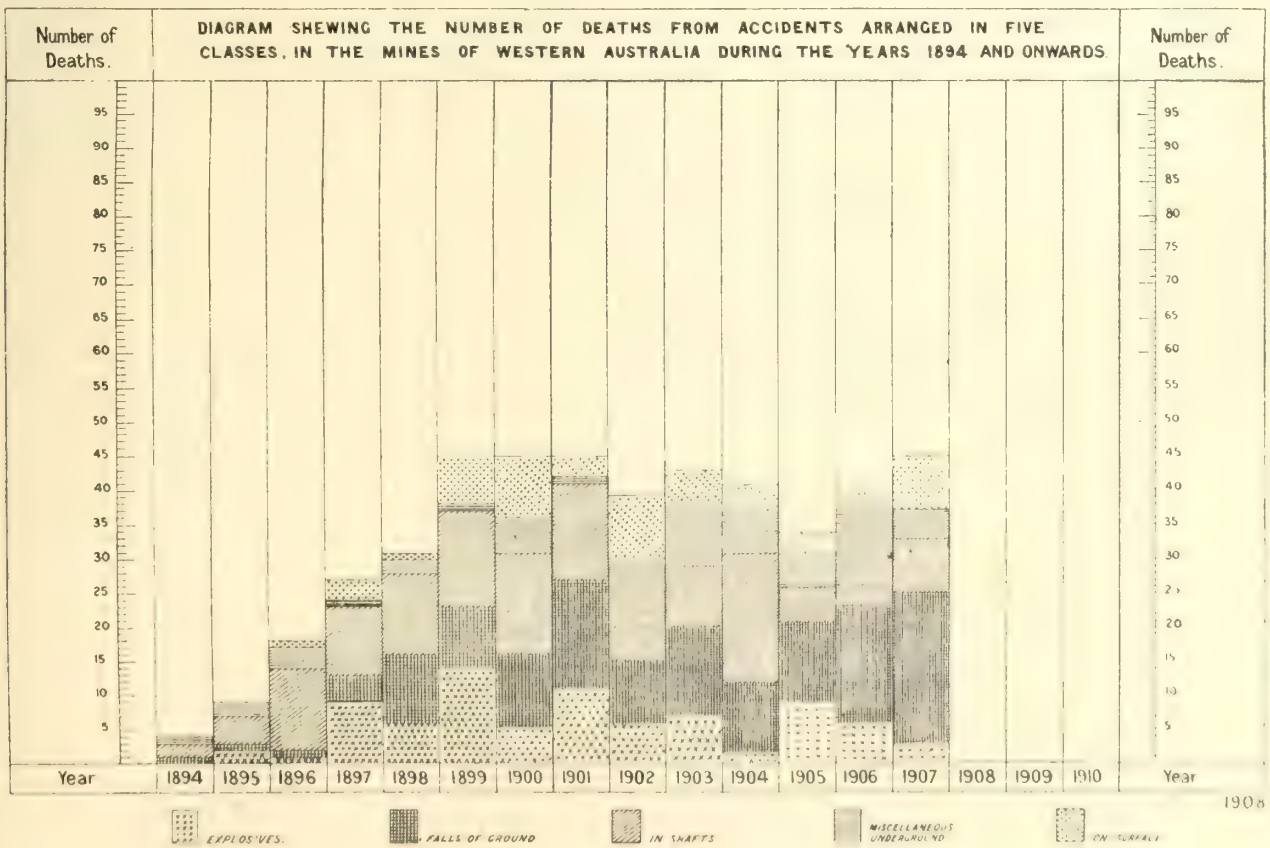
It may be noted that in 1906, 17 out of 40 deaths were due to falls of ground.

State Aid to Mining.

For nine years a system of state aid has been in vogue. There are now 29 state stamp-mills, 21 cyanide plants 3 slime plants (two of which were erected in 1907), 2 tin dressing plants, and one Huntington mill under Government operation.

Since the first state battery was started gold and tin to the value of £2,089,071 have been recovered at these plants; 505,286 tons of gold ore, producing gold to the value of £2,036,130 having been treated, and 31,166 tons of tin ore, producing tin to the value of £52,915. In addition gold to the value of £254,065 has been recovered by cyanide treatment, and £23,101 from slimes.

The tonnage of gold ore treated at state batteries has increased annually, until in 1907 the figures reported stand at 95,279 tons.



The revenue from all state plants was £91,274 during 1907, and the working expenditure was £91,351. Adding the sum of £1,622 spent in improvements, the net working loss for the year was £1,699. The plants used for the treatment of gold ore only show a loss on crushing of £8,724, and a profit on cyaniding and slimes treatment of £8,457. Expenditures from revenue in improvements and additions amounted to £1,622, leaving a net working loss of £1,889. To the end of 1907 the capital expenditure on state batteries and tin dressing plants was £237,029, and the working expenses for the entire period exceeded the receipts by £9,991.

The following statement, showing the sums advanced during the year 1907, under the provisions of the Mining Development Act, is worth reproducing:—

	£	s.	d.
Advances in aid of mining work	6,749	0	0
Advances in aid of boring	350	3	10
Advances in aid of crushing plants	1,000	0	0
Subsidies to provide crushing plants	2,300	11	0
Purchase of boring plants	2,490	16	2
Providing means of transport	1,052	19	11
Total	£13,943	10	11

In addition to the above, amounts totalling £7,832 11s. 4d. were expended from the Mining Develepment Vote on various matters for the assistance of mining, such as water supply, roads, subsidies to assist cartage or ore over long distances, drainage, timber tramways and subsidies for development work done below the 100-foot level in small mines.

Subsidies to the extent of £2,300 11s. were given to private crushing plants, the conditions being that they

crush for the public at fixed rates, in most cases conditions being imposed as to treating or purchasing tailings. The number of tons of ore crushed during the year was 38,143 tons. The receipts under the Mining Development Act, exclusive of interest payments, were £824 1s. 3d., made up as follows:—

	£	s.	d.
Refunds of advances	624	2	11
Sales of plant	199	18	4

Report of the State Mining Engineer.

The State Mining Engineer's report covers 19 gold fields. It is not our purpose to do more than notice a few outstanding features. There is much in each inspector's report for individual gold fields that is worthy of note. We shall be unable, however, to touch upon these beyond several specific paragraphs that deal with the equipment and work of operating mines.

In the Day Dawn division of the Central Goldfields division, the Great Fingall Consolidated Company operates the Great Fingall gold mine. The company is capitalized at £125,000 in shares of 10s. Up to the end of 1907 the company paid £1,543,750 in dividends. In 1907 alone it paid out £137,500. An account of its equipment should, therefore, be not without profit:—

Number of stamps dropping	100
	Feet.
Greatest depth of mine	1,880
Shaft sinking done in 1907	40
Drifting	2,432
Cross-cutting	739
Rising	2,884
Winzing	561
Diamond drilling	1,045½
	Tons.
Ore treated	261,057
Accumulated slimes treated	3,335
Accumulated slimes treated	1,085
	Fine oz.
Yield of gold over plates	56,451.093
Yield of gold from sands	19,502.630
Yield of gold from slimes	4,987.005
Yield of gold from concentrates	17,850.071
Yield of gold from accumulations	462.628
	Gallons.
Daily inflow of water about	30,000
	Fine oz.
Quantity of silver or other metals than gold	16,270.019
Average number of men employed under ground	332
Average number of men employed on surface	278
Cost per ton mined and hauled to surface	8s. 0.45d.
Cost per ton of ore treated	7s. 1,76d.

The working costs in this instance need fuller statement, but a rough analysis of the reported yield demonstrates that on a low-grade ore yielding about $7.60 in gold per ton (the yield of other metals is negligible), a handsome profit is obtained. On the plates about $4.30 per ton is recovered, or 56.6 per cent. of the gold content of the ore. Subsequent treatment, cyaniding, etc., accounts for the remainder. It is also noteworthy that the capitalization of the company is, roughly, $620.000. With 100 stamps installed the company returns to its stockholders more than their entire investment each year.

Interspersed throughout the reports of district inspectors are remarks concerning work in new and outlying regions. In the inland Mount Margaret and East Murchison gold fields, it is noted that many good prospects are spoiled because the men working them, though possessed of sufficient knowledge, have not enough capital to begin operations on a proper footing. Hence "they continue to work the richest ore until it

Table 7.

Dividends paid by Western Australian Gold Mining Companies during 1907 and Total to date.

gets below the payable stage with the appliances used and then abandon the place." So difficult is transportation in this part of the state and so costly are all kinds of supplies, that one enterprise abandoned a prospect as not then payable, although 1,357 tons of ore crushed yielded 1,309.71 oz. of gold over the plates of a five-stamp mill. In these remote mining fields camel teams are one of the principal means of transportation.

East Coolgardie gold field, with an area of only 532 square miles, occupies the first place as regards gold returns and dividends. During 1907 the gold mines of this field paid £1,489,697 in dividends. The larger mines are all served by railroad connections. Water is supplied by the Government, which controls an elaborate system. Close check is kept upon the daily consumption of water at the mines. Owing to the magnitude of mining operations the sand dumps around the mines are so high that they have become "a nuisance to the town . . . owing to the sands being carried by the wind." Arrangements are being made to sluice the residues away from the mines.

The Golden Horseshoe Company, operating in East Coolgardie, has erected a large and complete change house for its 882 employees. The building is fitted with wash-basins, shower-baths, swimming-pool, etc., and hot and cold water are laid on. The used water is pumped back to the batteries. It may be mentioned in passing that this company, with a capital of £1,500,000, paid dividends to the end of 1907 amounting to £2,520,000.

The inspector for the last-mentioned gold field adds a note of keen criticism regarding the competition among managers to report low treatment costs and large percentage savings. He first alludes to the apparent contradiction between the low values reported for tailings from certain treatment plants and the fact that several of the mines are erecting ore treatment plants. Further, he animadverts upon the disastrous effect of competition for reduction of figures of cost per ton. Although "by incurring further cost of 3 shillings per ton another pennyweight of gold, worth 4 shillings, can be extracted, there is a strong temptation for the manager nevertheless to let the profit go, rather than show costs 3 shillings a ton higher than those of his neighbors."

Among the reports of ore treatment costs we notice particularly favorable returns from two mines in the Yilgarn gold field. At the Never Never Gold Mine ore is being mined for 1s. 3d. per ton, milled for 3s. per ton, and cyanided for 3s. 6d. per ton, a total cost of 7s. 9d. per ton for mining and treatment. At the Queen's Cross Gold Mine, Coolgardie, ore is being mined and milled by a party of tributers at a total cost of 5s. per ton. It is remarked by the inspector that "plants are now erected to reap profits from the large and more persistent low-grade ore bodies rather than from the high-grade ore shoots which characterized the operations a few years ago."

General.

The operation of the Mines Regulation Acts, which are stringent and wholesome pieces of legislation, appears to have a salutory effect upon mining. Negligence on the part of employees and miners is discouraged by means of promptly levied fines. Reported cases of non-compliance with statutory requirements are investigated with little loss of time. Managers, shiftbosses and miners are included in the list of convictions.

Sunday labor is countenanced only where necessary. Legislation provides that only those who have secured special permits fro man inspector can Sunday work be legally undertaken. "In the case of one large mine," writes the State Mining Engineer, "I have been assured by the management that the cessation of Sunday work underground not only resulted in no loss, but was an absolute advantage to the mine in its working expenses."

We cannot in the space now at our disposal, touch upon the copper, coal and iron ore production of Western Australia. Before closing, however, in view of the recent discovery of scheelite in Nova Scotia, it may be timely to notice an occurrence of this mineral at Kundip, in the Phillips River field. Here a quartz vein carries gold and scheelite. After stamp-milling the scheelite was concentrated out and 17 bays were filled. Following are the particulars of the marketing:—

17 bags scheelite, gross weight..... 979 kilogrammes
17 bags scheelite—gross weight.... 979 kilogrammes
net dry weight. 943.38 "
net weight .... 950.7 "
Agreed assay: 75% WO_3 (tungstic oxide)
= 707.535 kilogrammes,
@ 45.50 marks per unit per 1,000 kilos
= M 3,219.30
Less charges.. 59.50

Net proceeds..	£139	1	2

This profit appears profitable on a consignment of less than a ton.

TALC AND SOAPSTONE.

Extract of advance chapter of mineral resources of the United States:—

Production.

Including the production of fibrous talc, most of which is quarried at Gouverneur, St. Lawrence County, N.Y., the total output of talc and soapstone in the United States in 1907 amounted to 139,810 short tons, valued at $1,531,047, an increase, as compared with 1906, of 19,166 short tons, or 15.9 per cent., in quantity and of $99,491, or 7 per cent, in value. The inceased production in 1907 was distributed among all the new important producing States.

The smaller percentage of increase in value was not due to any general decline in price, but to a larger proportion of the product which was sold in the crude or unmanufactured state, and in this portion of the product there was a decline in price. By far the larger number of the talc and soapstone quarries are operated or controlled by the manufacturers, and only a comparatively small part of the output is sold in the crude state. In 1907, however, there was an unusually large quantity sold crude, and part of this was low-grade material. The quantity sold crude in 1906 was 15,211 short tons, having an average value per ton of $2.65. In 1907 the marketed production of rough or unmanufactured soap-

stone was 25,538 tons, at an average price per ton of $1.36, so that while the quantity sold exhibited a gain of 10,327 short tons, or about 66 per cent., the total value decreased $5,712. The average price for ground soapstone was the same in 1907 as in 1906, while prices for manufactured articles or partialy manufactured materials were higher.

The talc and soapstone production is classified in the following four groups: Rough or crude, sawed into slabs, manufactured articles, and ground. A part of the crude product, represented in the first group, is sold to factories, and some of this is probably again included in the estimates of manufactured articles or ground materials represented in the other three groups, though duplication is avoided if possible. The relative quantities and values of these varieties produced in the United States during the last year are shown in the following table:

Condition in which marketed.	Quantity (short tons).	Value.	Average price per ton.
Rough	25,538	$34,625	$1.36
Sawed into slabs	4,822	91,668	19.01
Manufactured articles	23,484	648,475	27.61
Ground	85,966	756,279	8.80
	139,810	$1,531,047	$10.95

Production of Fibrous Talc in New York.

Practically all of the fibrous variety of talc produced in the United States comes from the vicinity of Gouverneur, St. Lawrence County, N.Y. It is all ground and is used principally for filling in the manufacture of medium grades of paper, though some goes into the paint trade, and some is used in the preparation of wall plasters, for which its fibrous character and heat-resisting quality make it well adapted. The production of fibrous talc in New York in 1906 and 1907 is shown in the following table:

	1906.		1907.	
Use.	Quantity.	Value.	Quantity.	Value.
Paper filling	61,672	$557,200	67,800	$626,000
Paint	61,672	$557,200	67,800	$626,000
Wall plasters	61,672	$557,200	67,800	$626,000

Imports.

The imports of talc into the United States have never been large, though the prices obtained are usually somewhat higher than the averages shown for the American product, and the values quoted for the foreign material are at point of shipment and are exclusive of freight and duty. The reason for these higher values may be attributed to the fact that only the fancy grades, which are used for the manufacture of face power and for medicinal purposes are imported into this country. The imports in 1907 showed an increase of nearly 50 per cent., both in quantity and value, over 1906.

Talc imported into the United States, 1902-1907, in short tons:—

Year.	Quan.	Value.
1902	2,859	$35,366
1903	1,791	19,677
1904	3,268	36,370
1905	4,000	48,225
1906	5,643	67,818
1907	10,060	126,391

Canadian Production.

There has been a small production of talc in Canada for several years, but the tonnage and values have varied considerably. In 1907 the production amounted to 1,534 short tons, an increase of nearly 25 per cent. over that of 1906, which in turn was more than double than that of 1905. The Canadian Geological Survey reports the production of talc in the Dominion for the last six years as follows:

Production of talc in Canada, 1902-1907, in short tons—

Year.	Quan.	Value.
1902	689	$1,804
1903	688	2,064
1904	840	1,875
1905	500	1,800
1906	1,234	3,030
1907	1,534	4,602

NOVA SCOTIA PERMANENT EXHIBIT.

In our last issue we gave a brief illustrated account of the mineral exhibits sent by the eastern and western provinces to the Canadian National Exhibition at Toronto. No detailed description of Nova Scotia's min-

Hon. C. P. Chisholm, Minister of Mines, Nova Scotia.

eral exhibit was included in this account for the reason that an article covering this ground had been published in the Canadian Mining Journal of May 15, 1907, and to this the readers were referred.

We decided at the time, however, that, although space would not permit printing a full list of the Nova

Scotian display, something more was due than mere mention.

The conditions under which Nova Scotia exhibited were unique. Hence we can, without making invidious comparisons, point out a few respects in which that province's Department of Mines is especially praiseworthy.

The Ontario exhibit was stronger, better arranged, and more complete than ever before. Alberta's exhibit sent from a longer distance than any other, was most attractive. But the mineral section was only part of a fine display of natural products.

The Quebec and New Brunswick exhibits were smaller than either Ontario's or Nova Scotia's. Both the first-mentioned provinces, however, had little time in which to get together a collection.

Nova Scotia's beautiful and striking collection of coal, gold ores, antimony, gypsum, and many other minerals representing the varied resources of our easternmost mining country, was most suitably housed. The exhibit is a permanent one. That is, it has been used at several expositions and is again to be used. But it is being constantly augmented by the addition of new specimens and improved by the replacement of old or broken specimens. From the Canadian National Exhibition it won two gold medals, one as an exhibit of economic minerals and one for its beautiful specimens of free-milling gold ores. Already it has a considerable collection of gold medals to its credit.

But the principal point to which we would allude is the fact that the N. S. Department of Mines is willing to go to the trouble and expense of preserving a permanent and portable mineral exhibit, in such form that it can, on a few days' notice, be sent to any quarter of the globe.

Such an exhibit is the most effective advertisement possible. It gives the public a complete view of the mineral possibilities of Nova Scotia. Its setting is so attractive that it compels attention.

Therefore, while Ontario especially, and Quebec, Alberta and New Brunswick generally, are to be commended for thier enterprise and liberality, it is due the Nova Scotian Department of Mines to say that they have set an example that should be followed by all our mining provinces.

The word "department" has a vague and impersonal sound. Behind departments there are live men. Accompanying this note is the photographs of the minister of Mines for Nova Scotia.

INAUGURAL ADDRESS.

By the President of the C. M. and M. Society of South Africa.

(R. G. Bevington, M.I.M.M., M.Am.I.M.E.).

I must first thank you for the honor which you have done me, and the confidence you have reposed in me in accepting me as your president for this coming year, and you may be sure that all I can do to further the interests of the Society will be done. I have been a member of the Society from its earliest days, and have its well-being and well-doing at heart. Prof. Yates has just joined, what he has termed the "Old Guard" of Past-Presidents, and I am sure you will all unhesitatingly agree with me that the Society is greatly indebted to him for the excellent manner in which he has carried out his duties during his term of office. The zeal and energy which has been displayed by your late Council in the carrying on of the business part of the work of the Society, and producing our valuable Journal, merits the highest praise, and I am very glad to see that it has pleased you to re-elect so many of its members to assist me during the coming year. Of the work of our Secretary, Mr. Fred. Rowland, one can only speak in terms of the highest commendation, and the Society is fortunate in possessing the services of one who is so keen in its interests.

It has been left to me by my predecessor to touch upon the work of the past year, the business aspect of which has been placed before you in your Council's Report.

With regard to the practical and scientific aspect, the members must have gained much knowledge from the number of instructive and interesting papers upon mining, milling, metallurgy, mine ventilation, stope drills, and so many other subjects which fall within the scope of the Society's work, which have been read before them. I am very pleased to see that we have had so many papers contributed by members in distant parts of the world, for that shows the hold which our Society has upon its members though far away, and the interest which they take in contributing papers upon subjects which they know will afford us food for reflection and healthy criticism, and I trust that the ensuing year will be as productive in this respect, and even more so.

The increase in mining members and the number of able papers on mining matters which have been given us has fully justified the course taken in adding the word "Mining" to the title of the Society. I feel sure that there are still many more mining men who will become members when they realize that the Society is not a closed one, but is open to all to whom the subjects dealt with are of sufficient interest to cause them to wish to join. It is through the interchange of views at our meetings, and in our Journal, that one's interest becomes carried into other branches of our work than that particular one with which one is perhaps specially occupied, and thus an incentive is given to learn more of the work being carried on by others and the difficulties which they have to contend with, which all tends to cultivate a broader and more tolerant frame of mind.

In reflecting upon the progress of mining and metallurgical work upon the Witwatersrand, having been associated with these fields from their very early days, it is most interesting to me to look upon the great advance which has been made in every branch of the industry. Magnificent headgears and huge hauling engines have taken the place of the old horse whims and whips which I remember. Large shafts carefully planned and proportioned to the work required of them have taken the place of open cuttings. Batteries of

hundreds of stamps of heavy weight have supplanted the 10 to 20 light stamp mills, and in doing all this, the best talent and scientific knowledge obtainable has been brought to bear, with a result of which all who have been engaged in the work must feel justly proud.

The advent of the cyanide process marked a point from which the greatest strides in the metallurgical part of our work have been made, and this process has afforded food for deep thought and research on the part of our chemists with the result that the whole method of application has been most carefully studied and worked out, but that is not saying that there is no opening for further improvements.

Chemical researches in the matter of strength of solutions employed, the combating of cyanicides, and the treatment of zinc to obtain better precipitation, have resulted in replacing the strong solutions which were at first deemed to be necessary, by what then seemed to be solutions of such little strength as to be useless. This, assisted of course, by reductions in manufacturers price, has resulted in greatly reducing the cost per ton treated, of what is still the largest item in the cost of treatment, viz., cyanide. Researches have proved that these weaker solutions are as effective and indeed more advantageous in that baser metals, which may be present in the ore, are less readily taken up by a weak than by a strong solution, and in this connection it may be remarked that the more rapid, and, at the same time, thorough, the treatment can be made, the less the amount of base metal which will pass into the solution.

Slimes, the making of which we at one time strove to avoid, are now almost welcomed, and the evolution of their treatment in a satisfactory manner has added enormously to the quantity of ore of low grade which may now be treated at a profit, so much so that rock is now being milled, and yielding a very handsome profit, having a less original content of gold than the assay value of tailings from the same class of ore which were refused by a cyaniding syndicate many years ago, as not being of sufficiently high value to be worth treating. One must not overlook the process for re-treating old tailing dumps, nor the fact that solutions very weak in cyanide, but holding minute quantities of gold and which at one time were looked upon as waste, are now passed through extractor boxes before final disposal, in order to endeavor to recover every grain which may be recoverable.

Turning to present practice. Milling work on the Rand seems to have settled down to a great uniformity of practice in the conducting of the general operations, though, of course, the question of greatly increasing the weight of stamps is occupying the attention of some of our leading metallurgists, and in this connection I would refer to the new mill of the Simmer Deep G. M. Co., the weight of the stamps in which will be 1,700 lb. In this case will also be put to the test the advisability of dividing up a large mill into separate units of 10 stamps, each unit being electrically driven. I cannot but think that this scheme will prove an undoubted success. As you will doubtless learn more about this, one of the newest plants on these fields, from another source, I will leave the matter to be dealt with by those more able to do so than myself.

Cyaniding, too, would appear to be conducted upon generally recognized lines in the carrying out of work, but still the energy of our members is always being devoted to the bringing out of some further improvements.

Slimes, which I have before referred to, as having been at one time looked upon as a bane and a bugbear, are now so successfully, and, one may say, so easily treated, that if the general grade of the ore on these fields are higher, it is quite a question whether the practice of all sliming would not be resorted to. In the near future I think we shall see some improvements made in the means for handling sands and slimes, so as to make plants less cumbersome and extensive, thereby reducing the initial cost of same, and it seems possible with the many improvements which are being made in slime filters that the decantation process may be superseded, or at least greatly assisted, by filters of the pressure or vacuum type in order that the slimes residues may pass out of the works deprived to the fullest extent of their content of soluble gold.

Tube milling, which on its introduction met with many objections, seems to have held its own and with very beneficial results upon the gold production and the lowering of the value of the final residues, but I would suggest that there is yet work to be done in discovering and defining the most suitable size and shape of the mill and the correct speed at which it shall be driven, also with regard to the diameter of the discharge outlet as governing to a certain extent the length of time which the pulp shall remain in the mill before making its exit therefrom. I am also inclined to think that a means should be provided for varying the number of revolutions, as the internal diameter becomes greater through the wearing of the lining, for it does not appear to be theoretically correct that what is the correct speed for one internal diameter is correct for a different diameter. The use of tube mills as secondary crushers, or rather grinders, has resulted in greatly increasing the duty per stamp owing to the possibility of using screening in the battery of larger mesh than would otherwise have been economically possible, and withal has reduced the value of the final residues.

In mining work there is always something new being done in the application of methods and overcoming the difficulties of getting the broken ore from the working places quickly to the surface. We are all looking to the near future to give us a handy stoping drill, and in this connection I would refer to the forthcoming stope drill competition. This competition will, I am sure, be most closely followed by mining men, not only here, but in all parts of the world. The benefit of the results to this community, provided that a reliable, light, efficient, and economical stoping drill, and one which will not be costly in repairs, can be found, will be immense, as it is the cost of mining which tells so much against many low grade propositions. The conditions and regulations for the trials appear to have been drawn up with the utmost care, and it is hardly conceivable that any question or contingency can arise under them which has been overlooked and not provided for. The composition of the committee, both as regards the members nominated by the Transvaal Government and those nominated by the Transvaal Chamber of Mines, is such as to inspire complete confidence in those who may be competitors, and also in the whole of the mining community and the public, who will await the findings and awards with the keenest interest.

The metallurgy of gold is simple compared with the problems which beset the metallurgist who engages in the work of dressing base metal ores and winning their contents. Our country is without doubt very highly

mineralized, and although not much has as yet been done in this direction, there will rise up in the future a large base metal industry, and one would, of course, wish to see the youth of South Africa in a position to take an active and leading part in such an industry. This it will not be able to do without having gained its knowledge in a practical and thorough manner, and this is the advantage which the Transvaal University College will offer in its new building, by means of ore dressing and metallurgical laboratories, and I counsel all those who desire to be able to take their due part in the development of the mineral resources and wealth of the country to lose no time in undergoing a thorough course of tuition in this excellent institution, under the direction of the able and energetic staff of professors which is associated with it. There is no place in up-to-date practice for the out-of-date worker. It is becoming more and more essential that a man should know both the theory and practice of his profession if he would compete with and rise above his fellow-men, and I venture to say that men who have had a good technical and practical training will be more and more in demand to the exclusion of the rule of thumb worker.

With regard to the ore dressing and metallurgical laboratories, there will, of course, be certain items of plant, models, etc., required beyond those which are now possessed, and it is to be hoped that money for this purpose will be unstintingly provided, in order to place the college in a position to compete with oversea mining schools. It is also to be hoped that the ore dressing plant there may be thrown open to all who may be competent to use it, and by this means assist prospectors, miners, the mining houses, etc., in short, be of benefit to the country generally. At present ore is being sent out of the country to be treated, but several small plants are now, or are about to be, erected in order to treat the ore on the spot.

That the base metal possibilities are receiving attention, and that the output from the various sources is growing, may be seen from the report of the Government Mining Engineer for the year ending June, 1907, wherein it will be found that in the year 1906-07 base metals were produced of an estimated value of over £90,000 as against £19,500 in 1905-06, and I trust that in the next report a further increase will be shown.

The fine new building of the Transvaal University College, over which your retiring president, Prof. Yates, was kind enough to conduct me recently, is nearing completion, and I understand it is the intention to provide rooms for the offices of the various technical societies. This, I consider, will be a very good thing, as it will bring us all together under one roof, and will, doubtless, lead to the establishment of a common room, open to the members of the various technical societies, where technical papers and the journals of similar societies all over the world will be on view, and such meetings of scientific men on a common plane will assuredly lead to that co-operation among scientists of every branch which is so desirable and necessary for the progress of science in general, and which should eventually make for that closer union of all the scientific societies in South Africa, which is so much to be desired.

(*To be continued.*)

DREDGING IN THE YUKON.

Abstract of article in the Mining and Scientific Press. By T. A. Rickard.

Frozen ground is generally supposed to be a fatal obstacle to the profitable dredging of gold-bearing gravel; it is usually assumed that all the alluvium of the Far North is in a perpetually frozen condition; in consequence, the opinion obtains even among well informed engineers that dredging in the Yukon is at best a costly experiment. The following data, recently gathered by personal observation, will be of interest to the profession and to others engaged in this branch of mining.

The first dredge to go to work in the Yukon was that of the Lewes River Mining & Dredging Co.* This machine was built to operate on the Cassiar bar of the Lewes river, a tributary of the Yukon, in 1899. In 1901 the dredge was moved to Claim No. 42 Below Discovery on Bonanza creek, and in 1903 up the creek to the Discovery group of claims. Last year the dredge was moved down to No. 6 and 7 Below Discovery, where it is now. On claim No. 42 the work was done on the basis of a 50 per cent. "lay," that is, the gross output was divided between the claim-holder and the dredging company, but in every other instance this dredge worked on ground belonging to its owners. This machine is now out of date, but it has given excellent service despite hard treatment. It was built by the Risdon Iron Works of San Francisco, and has 3¼ cu. ft buckets, open-connected, giving a capacity of 900 cu. yd per day. The of the Risdon type, that is, a bucket-conveyor, which the superintendent, Edward Simpson, says has not given a minute's trouble. For a short stacker of small capacity such as this, the bucket-conveyor is well adapted. The digging-depth reaches to 20 ft., that is, a maximum depth below water of 18 ft. About 4 ft. of bed-rock is removed, up to a maximum of 6 ft., as determined by panning the material brought up by the buckets. The dredge is operated by steam power obtained by burning 3 cords of wood per day, or 85 cords per month. The season averages 160 days. The dredge at the time of my visit was extracting 100 oz. gold, at $15.50 per oz., per day, so that the yield must average $1.70 per cubic yard.

* * * * * *

The ground is thawed artifically ahead of the dredge. It has been ascertained that the ground will keep warm for a month, so it pays to keep the thawing at least that much ahead of the digging. In any part of the creek that has been previously worked, as by drifts, accumulations of ice are found, due to seepage of water into voids and the effect of the ground-ice. In gravel that has not been molested the conditions are more favorable, for there the seasonal thaw will conquer the frost, if once the covering of moss be removed. The thawing was in progress just in front of the dredge, the steam-points being distributed at intervals of 4 by 8 ft. As the season progresses the interval is increased; at first, in April, it was 4 by 4 ft., and this was widened until by June 20, it had become 8 ft. one way and 4 ft. the

* At the present time there are 17 dredges at work in the Yukon Territory.

other. On July 17, the day of our visit, the seasonal thaw had softened the ground down to 7 ft., so that the points had that much less to do. The cost averages 12c. per cu. yd. In virgin ground an interval of 24 ft. for the points would be effective, but it does not pay to take chances wherever there are old workings, for the frozen pillars, topped by patches of moss, constitute the best of the gravel, and in old workings there is an agglomeration of gravel and "muck," with ice, making it imperative to thaw the whole mass. It is poor economy to take chances, for not only does the frozen ground imperil the dredge, but it prevents extraction of the gold. In virgin ground, after strippng the moss and mould, the natural thaw would reach to 14 ft. at the end of two seasons. The dredge has extracted about $700,000 in its various applications. By a life of seven years, that is, seven short seasons, and a probable further usefulness to the end of next summer, it has demonstrated what good service even one of the older and smaller machines wil give under adverse conditions.

The Canadian Klondike Co. commenced work on the Boyle Concession three years ago, and began dredging in August, 1905. This boat, built by the Marion Steam Shovel Co., has done most satisfactory work, considering that it was designed in 1904, since which date much has been learned concerning details of dredge construction. It is interesting to state that this dredge in the valley of the Klondike river is practically a counterpart of the "California No. 3," at Oroville, operated by the Oroville Dredging Co., although strengthened in parts, and with a better screen-arrangement. The record of the dredge on the Klondike is fully as good as that working under the supposedly more favorable conditions in California. In 1906, from May 9 to October 23, this dredge handled an average of 2,935 cubic yards per day; in 1907, from May 15 15 to October 9, this dredge dug 3,490 cubic yards per day. It is known that a good profit was made in both these seasons.

This dredge is the only one at work on the Boyle Concession, a tract covering 40 square miles, and extending for 6¼ miles along the Klondike, so as to cover from half a mile to one mile wide of alluvium. The gravel is 22 to 35 ft. deep, and bedrock is soft schist, so that the buckets dig into it to a depth of 4 ft. No artificial thawing methods are employed, the ground having been softened by the successive seasonal thaws, following the removal of the overburden of moss by freshets sweeping across the flat valley. A little frozen ground was struck near the edge of the channel, without damage to the dredge, and without benefit to the clean-up; the buckets cut into it and excavated it successfully, but the fragments of frozen gravel were not disintegrated in the screen, passing onto the tailing-pile without the extraction of any gold that they might have contained. With the exception of this incident, the frozen ground, which is such a bugaboo to dredge-masters in the North, has played no part in the record of this particular dredge.

It remains to add that the buckets are each of 7 cubic feet capacity, close-connected, so that the machine handles 3,900 to 4,00 cubic yards per day. Power is applied through the medium of electricity, generated by a 400-kw. Westinghouse generator, making 3,600 revolutions per minute direct-connected to a Parsons steam turbine. Wood at $7.75 per cord is burned in water-tube boilers, supplying steam at 165 lb. pressure.

* * * * * *

The Yukon Gold Company will have seven dredges in operation before the close of the present season. The three dredges first built had buckets of 5 cu. ft. capacity. The four new dredges, of which two are completed, and two are nearly finished, have buckets of 7 cu. ft. capacity, and they have been designed to fit local conditions. On July 15 I visited one of these larger dredges, namely, that known as No. 6, on Bonanza Creek, at 90 Below Discovery.

* * * * * *

Dredge No. 6 of the Yukon Gold Company is an up-to-date machine of the most approved design and built by the Bucyrus Company, of South Milwaukee. Going aboard the dredge, it is noted that the buckets have lugs designed to transmit the digging-stress from the lips to the base, and to relieve the rivets from excessive strain. Mr. E. E. McCarthy, the dredge superintendent, informed me that the lips of the bucket were made of Manard manganese steel, the base of chrome-nickel steel, and the hood of cast-steel. Each bucket has a capacity of 7 cu. ft., and as the speed over the tumbler is at the rate of 23 buckets per minute, the capacity of the dredge is from 90,000 to 125,000 cu. yd. per month, depending upon conditions. These conditions include, more particularly, the depth of the gravel, the character of the deposit, and the amount of bed-rock excavated.

* * * * * *

Every part of the dredge is of the most approved construction, for the length of the season in the Yukon country is so short as to make experiments inadvisable. The choice of design is the outcome of wide experience in this branch of mining on the part of O. B. Perry, the general manager of the Yukon Gold Company, and it represents the best type of machine now at work in the North.

A part from economic conditions, which vary all over the world, the distinctive feature of dredging practice on the Yukon is the necessity for overcoming the frozen condition of the ground. This a geologic frost as distinguished from the seasonal frost.

The seasonal frost, as measured on ground that has been thawed in summer, ranges from 3 to 5 ft., but the geologic frost extends to a depth of 230 ft., if not more, wherever the ground is wet, as in valley-bottoms. On the other hand, the warmth of the short summer, lasting 4 to 4½ months, will thaw the ground to a depth of 4 to 7 ft., according to local conditions, the chief of which is the nature of the surface-covering. In two seasons the frost in a gravel deposit may be conquered by the seasonal thaw to a depth of 10 to 22 feet.

The Northland is covered by a blanket of moss and loam due to the decay of vegetation. This overburden is called "muck" by the miners because when it melts it runs like thin mud, for it is composed of 24 to 40 per cent. organic matter and 60 to 70 per cent. ice. When either the summer sun or artificial heat strikes this black blanket, it disintegrates and is readily floated on the running stream. Being a mixture of organic matter and ice, it makes a perfect insulator against heat and protects the underlying frozen ground from the warm air of summer. The thickness of this frozen muck varies from a few inches to 40 ft., the maximum being in gullies where it has accumulated by sliding from adjoining hillsides. Two feet is an average thickness.

It is obvious that before the seasonal thaw can become effective, the blanket of moss must be removed. This is done naturally by freshets and by meandering streams; it has been done in a general way as an incident in ordinary mining operations along the creeks, and it will be done systematically both by ground-sluicing and also, much more rapidly, by hydraulicking. Where time is not an immediate factor and where bed-rock is not more

than 15 ft. deep, a gravel deposit can be thawed to bed-rock in two seasons by simply removing the cover of moss and loam so that the summer heat may get an opportunity to penetrate. But, on the other hand, where dredging operations cannot wait for such a slow method, or bed-rock is deeper than 15 ft. or where old workings exist, it becomes necessary both to accelerate and to perfect the thawing process by the aid of artificial methods. This is done by the application of steam.

By introducing steam into the frozen ground, the ice is melted; the more water (that is, ice) there is in the gravel, the more steam will be consumed in converting water from its solid to its liquid state. Ice is a non-conductor; rock is relatively a good conductor; therefore, the less water the gravel contains, the more easily it is thawed. The stones retain the heat imparted to them so as to radiate it slowly into the surrounding mass.

* * * * * *

Thawing the frozen ground is a temporary procedure. As soon as sufficient water is made available by the completion of a main ditch-system, it is intended to strip the covering of moss by the use of water under high pressure. The ditch and pipe-line of the Yukon Gold Company is now approaching completion, and the water will be ready for stripping early next season. Thawing will be discarded at the close of next season, except in isolated spots where the water cannot be used advantageously. The method of using water in preparing the ground for dredging will be as follows: First, sotck-lines will be laid along the edge of the creek carrying water under high pressure, tapped from the main trunk line. The moss and muck will be stripped by "piping" (that is, the use of a large volume of water under pressure), driving from both sides to a longitudinal cut, down the centre of the claims. See Fig. 1. This work will be carried forward about two miles ahead of the dredges. When the ground has been stripped, the water will again be applied (at the lower end first), so as to cross-cut the gravel with trenches at intervals of from 20 to 50 ft. The effect of this exposure of faces of gravel to the air is to accelerate the natural thaw. After the cross-trenches have been made, the longitudinal trench will be deepened so as to drain the entire area. The depth of the trenches, and th extent to which this work is carried, will depend upon the depth to bed-rock and the rate of thaw. See Fig. 2 and 3. Experience thus far indicates that when the stripping has been completed, not much trenching is necessary to carry the thaw to bed-rock when the gravel is not more than 18 or 20 ft. deep. Each successive season will extend the thaw farther, so that the depth and amount of trenching will depend upon the nearness of the dredge. By this method, the total cost of preparing the ground for dredging should not exceed 5c per cu. yd., for there is no installation and maintenance of sluices, and many of the other expenditures incidental to hypradulic mining are lacking. The actual work of mining is done by the dredge; the amount of ground moved in the preliminary operation being small, compared to the yardage dug subsequently by the dredge itself. By thus making the most of the natural thaw, and preparing the ground for rapid dredging, the total cost of mining the gravel should not average more than 20 to 25c per cu. yd. The result obtained with artificial thawing in advance of dredging actually shows a cost of 19 to 35c per yd. The more the natural thaw is used to fight the natural frost, the smaller the expense will be, and the less the final cost of operation.

As a matter of interest, the following data concerning the operations of the No. 6 dredge may be quoted: The width of dredgeable ground, reaching from claim No. 88 Below Discovery on Bonanza Creek to No. 104, ranges from 500 to 1,300 ft. The depth to bed-rock averages 16.7 ft. The bed-rock itself is sericite-schist, with quartz stringers, decomposed so as to be dredgeable to 4 or 5 ft. deep. The gravel is small; immediately above bed-rock, where the stones are largest, the size is rarely over 6 in., with a few boulders that attain a weight of 100 lb. apiece. The length of campaign here is one-third of a year, and the dredge is expected to be in service for a period 1½ times as long as in California, that is, the actual working time is one-half that of a dredge working at Oroville. Depreciation in the Yukon is based on a service of 12 seasons, equivalent to 5 years of actual operation; in California it is 10 years.

During the 22 days of July that had elapsed up to the date of this writing, the No. 6 dredge had dug 51,952 cu. yd., from the start of the work. The total cost was $11,728; the total yield was 2,718.48 oz. gold, worth $44,281; the operating profit was $32,553. In the costs are included $1,443 for labor, $50 for repairs, $190 for supplies, $1,500 for depreciation, $1,752 for selling charges (including also tax, express and treatment) on the gold. Power cost, $1,500, this being based on 300 hours at an average load of 200 kw. hr., or 60,000 kw., at 2.51c per hour. Thowing to the amount of 4,086 sq. yd. cost $4,168. Repairs and supplies are low as compared to an average operation. If this item is increased by $1,500 to $1,800 per month for the season, the extra cost would be, say, 2½c per yard. The allowance for repairs and depreciation together is then $3,500 to $4,000 per month.

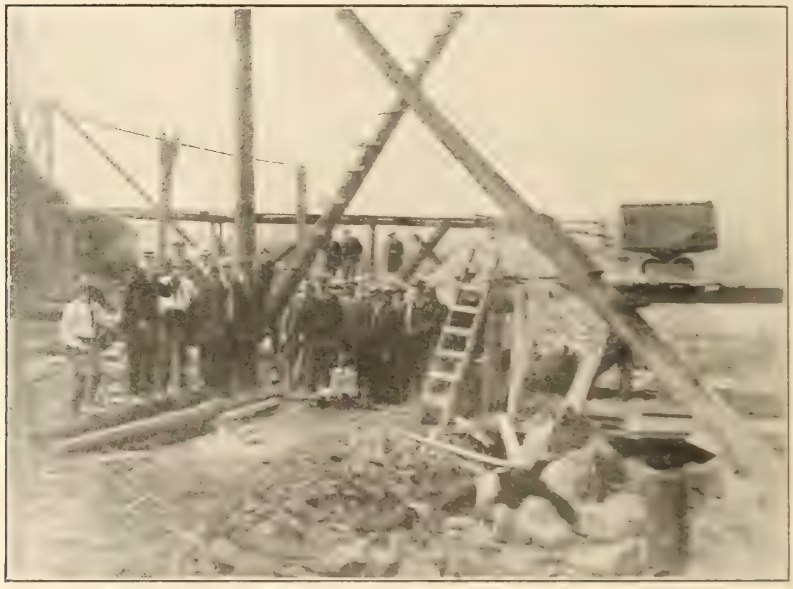
It is noted that the thawing by steam-points covered 4,086 sq. yd. of bed-rock at a cost of $4,168, to which must be added the preliminary sluicing-cost of $800. Of the total yardage dug by the dredge, only 56 per cent. required artificial thawing; in consequence, the net cost of thawing was only 9½c per cubic yard dredged.

The work of the 22 days showed a return of 85.3c per cubic yard; the cost was 22.6c, and the gain 62.7c. Adding 2.5c more for repairs, the cost becomes 25.1 and the profit 60.2 cents per cubic yard. It is interesting to state that the estimate based on the examination of this ground was 60 cents gross per yard. The actual return thus far affords an encouraging result; for the cost is as estimated, while the profit is greater. It must be remembered that the No. 6 dredge is a new machine, just put into operation. As the season progresses, the capacity will be increased; it ought to be at least 80,000 cu. yd. per month, as against the rate of 70,000 recorded for the period reviewed. At Oroville, dredges of the same type are digging from 120,000 to 150,000 cu. yd. per month in ground yielding 12c. per yard at a cost of 5c per yard.

At the present time the Yukon Gold Company has five dredges in operation and two more nearly ready to start. The economic results so far this season are uniformly good, and compare favorably with the original estimates. Difficulties due to frozen ground are almost negligible; the troubles that proved so annoying last year were due chiefly to inadepate equipment. While some artificial thawing by steam will always be necessary, in spots, and while such thawing is costly, the proportion of ground requiring the use of steam-points will be steadily reduced. The application of water under pressure, as already described, will become an important factor in diminishing the expense of preparing ground for dredging. On the whole, it is apparent that frozen ground is not the terror it has been represented to be, on the basis of the first experience with dredging in this region.

The Canadian Klondyke dredge showed a seasonal cost last year of 16½c. per cubic yard, digging ground

that needed no artificial thawing. I am informed, on good local authority, that the Bonanza Basin dredge, at the mouth of the Klondike River, is now doing well, in rich ground. The dredge at the mouth of the Forty Mile River, belonging to the Consolidated Gold Dredging Company of Alaska, is also said to be working at a profit. The Yukon Gold Company's dredges are working at a total cost, including thawing, of 19 to 35c, and the expense will be reduced next season to an average of, say, 20 cents. The gravel is rich and patchy, as rich gravel always is; but there is every reason to believe that some of the claims on Hunker and Bonanza Creeks will give yields constituting a new record in this branch of mining.



On the whole, the prospects for dredging in this region are vastly better than they were a couple of years ago. Where failures have been made, they were due mainly to light machinry of inferior design, hindered by inadequate equipment, rather than the poverty of the ground or natural obstacles to mining operations.

COBALT VISIT OF C. M. I. EXCURSION.

The Reception Committee of the Cobalt Branch of the C. M. I. was as follows: M. T. Culbert, O'Brien Mine; E. L. Fraleck, Cobalt Lake Mine; R. W. Brigstock, Drummond Mine; T. Jones, Buffalo Mine; R. P. Rogers, Coniagas Mine; G. McNaughton, Trethewey Mine; S. H. Logan, manager Canadian Bank of Commerce; Hugh Park, Nipissing Mine; D. B. Rochester, Cobalt Lake; R. A. Bryce, Silver Queen; Arthur A. Cole, T. N. O. Ry., chairman.

Before arrival at Cobalt the party was divided into foud groups, and on arrival each group was taken charge of by two guides.

During the morning (Sept. 5) the following mines were visited: Buffalo, Cobalt Lake, Coniagas, La Rose, Nipissing, Right of Way. The following mills were also visited: Buffalo, Coniagas, Muggley.

Mining Engineers at Crown Reserve.

Luncheon was provided for the party by the following mines: Coniagas, La Rose, Nipissing, Right of Way.

In the afternoon the private train was run out to the end of the Kerr Lake branch, and the following mines were visited: Lawson, Crown Reserve and Kerr Lake. The fine collection of native silver from the Nova Scotia had been brought over and was on exhibition at the Kerr Lake Mine.

Canadian and British Mining Engineers' Train at Cobalt.

Train was taken at 6 p.m. and the party run north, where they were entertained by the towns of New Liskeard and Haileybury.

Sunday morning (Sept. 6th) the train was run down to Temagami, where the Belle of Temagami was awaiting the party. A pleasant run up the lake to Temagami Inn, where luncheon was provided, compelted the morning. After having a look at the Hudson's Bay post at Bear Island, an early return was made to TemagamiS tation. Mr. T. B. Caldwell conducted the party over his Iron Range, and at 6.30 the train pulled out for Sudbury.

The Cobalt Reception Committee presented each guest with a souvenir, which consisted of a small disc of refined metallic cobalt, on which was enamelled the word Cobalt, fixed to a nugget of native silver. The metallic cobalt was presented to the committee by the Orford Copper Company of New York. Besides this each foreign society which was officially represented was presented with a collection of rocks and ores of the Cobalt district. Chairman A. A. Cole, who was responsible for this idea, has got together a number of these collections. They are valuable aids in the study of the district.

BOOK REVIEWS.

Genesis of Metallic Ores and of the Rocks which enclose them—by Brenton Symons, F.C.S., etc. 494 +XXXIII. pages. 154 illustrations. Price 7s. 6d. net. Published by "The Mining Journal," 46 Queen Victoria Street, London, E.C., 1908.

Technical treatises, professional text-books, brochures, monographs, reports, and theses are usually read under compulsion. The student in his salad days has before him the soul-searching examination. The mine manager or the consulting engineer is forced by the competition of his fellows to keep abreast of the times. The book reviewer (an odious beast at best) must earn his stipend.

It may then be postulated that few technical or scientific books are perused for refreshment or recreation. Consequently, or conversely, it is unusual to find books of this sort that are in and of themselves refreshing. Mr. Symons' "Genesis of Rocks and Ores" is refreshingly readable, and, therefore, unusual.

Mr. Symons' object has been to clothe his chosen topic with interest; to avoid superfluous technicalities; and to give the public a book that it can and will read. Considering the volume from this point of view it is vastly more approachable than the polysyllabic patter of our arch-enemy, the modern geologist. In fact Mr. Symons' book is suspiciously easy to understand., therefore he will merit the displeasure of those gentlemen whose function in life is the interdifferentiation of innocent magmas, the contortion of unsuspecting anticlines, or the erosion of unoffending landscapes.

"Genesis of Rocks and Ores" is divided into three books as follows: Book I., Sedimentation of Rocks and Ores; Book II., Metamorphism of Strata; Book III., Segregation of Metallic Ores in Veins. Each book is subdivided in careful and logical sequence. From examination of the table of contents it is seen that the author considers his subject as an organic whole with articulated branches, rather than as a disjointed assemblage of incompletely related phenomena.

Therefore the reader is carried naturally and easily from chapter to chapter and from book to book, for Mr. Symons possesses an exceptionally fluent style and has at his disposal a comprehensive vocabulary. Nor is his style devoid of charm. On the contrary, there are passages that are unquestionably graceful, powerful and lucid.

At pleasing intervals there are liquid inclusions of verse, which neither detract from the appearance nor impair the value of the work.

Lest we be tempted into unprofitable discursiveness, we wish to conclude with hearty approval of Mr. Symons' attempt to popularize a difficult and complicated department of science. The book is written by one whose whole heart is in his work.

The result is what one might expect—a book that shows every evidence of careful workmanship, profound erudition, sound judgment, and good taste.

We do not hesitate to recommend the "Genesis of Metallic Ores" to the mining fraternity in particular and to the reading public in general.

The Miners' Pocket Book—A reference book for engineers and others engaged in metalliferous mining—by C. G. Warnford-Lock, M. Inst. M. M., F.G.S. Fifth edition. Entirely rewritten. Numerous illustrations. 624 pages...Price 10s. 6d. E. & F. N. Spon, Limited, 57 Haymarket, London, 1908.

As the author explains in his introduction, the professional mining man is constantly confronted with difficulties. He can carry with him no reference library. He must, in most instances, rely upon his own unaided judgment. Many pocket reference books have been published to aid the engineer in the field and to supply otherwise inaccessible data. Only long experience can indicate just what material should be included in such volumes and what omitted.

Mr. Lock's "Miners' Pocket Book" has entered upon its fifth edition. It has been completely rewritten. Numerous deletions have been made, and much has been added.

The question of suitable field-books is one of paramount importance to the mining engineer and to the prospector. We therefore think it not out of place to present a rough view of the contents of this particular pocket book, and to examine more critically one or two of the sections into which it is divided.

Beginning with a section on power, in which comparative costs of all varieties of power are given, power transmission, weights and measures, prospecting, mine surveying, drilling, blasting, shaft-sinking, developing, mining methods, hauling and hoisting, unwatering, ventilation, sanitation, lighting, signalling, aid in mining accidents, are successively disposed of. A substantial group of tables for the identification of minerals, a list of useful books and a glassary, complete the volumne.

The illustrations, type, and paper are good. The cover is strong and durable, an important consideration in pocket books.

Naturally, as one of the most important divisions of the hand-book is that in which prospecting is described. Rough estimates are given of the expense per acre, etc., of clearing land. The methods of exploring superficial and deep deposits are outlined, and an excellent summary of diamond drill practice is included. The calyx drill is not touched upon. The crude Australian "dolly," or home-made prospecting stamp, is described, but no reference is made to the many excellent types of prospecting stamps manufactured on this side of the Atlantic. Indeed, although prospecting is taken up in a practical manner, yet the author's treatment of the subject is scant. Much material that is essential to the beginner is omitted.

In contrast to the section on prospecting, those devoted to mine surveying, drilling, blasting, shaft-sinking, trenching, etc., are up-to-date, lucid and comprehensive. Such modern developments as square-set timbering are given due prominence in the text and by means of diagrams. A short explanation of the uses of underhand stoping is one of the best passages in the book. In short, those parts of the volume that have to do with actual mining operations are most creditable. But they are, as is inevitable with English publications, tinged strongly with the methods and terminology of English mining districts along with Australian and South African modifications. Sometimes the charge of provincialism could be preferred with justice.

The chapter on "Fellow Aid in Mining Accidents," a most decidedly instructive addition to the volume, lends especial value to the hand-book It is brief, but

well calculated to help the prospector or miner out of otherwise serious contingencies.

These random remarks do justice neither to the incidental shortcomings nor to the outstanding excellence of "The Miners' Pocket Book." It may be but fair to sum up our impressions by saying that Mr. Lock's sins of omission do not affect the volume seriously. On the other hand, the book has in it a great deal of mining information that the mining engineer cannot carry in his head, and much, also, that he is supposed to carry but usually does not. Imperfections will exist in books as long as they persist in mankind. Mr. Lock's book is not perfect; but it is, by long odds, the most useful pocket book that we have seen for some time.

Cyanide Processes. By E. B. Wilson, E.M. Fourth Edition, revised and enlarged. 12 mo., cloth $1.50, 249 pages. John Wiley & Sons, New York.

Like a widower that has survived three wives and has consummated a fourth matrimonial arrangement, a book that sees four editions must have solid virtues.

The scope of cyaniding has widened tremendously since the first edition of Mr. Wilson's book was published. Its application is yet by no means universal. The fact that the limitations of the process are now more exactly known has eliminated many costly blunders.

The most marked feature of recent practice is the successful treatment of slime by means of filter-presses, distributors, agitators, and decantation. This topic Mr. Wilson treats in a new chapter, the longest in the volume.

No superfluous matter is included in "Cyanide Processes." Mr. Wilson has eschewed the customary device, to which authors not infrequently resort, of padding their text with extracts and details of construction from manufacturers' catalogues. He wisely leaves all details of plant construction to the discretion of the engineer and millwright.

The practice of cyaniding, the chemical and mechanical principles involved, the essentials of the subject, Mr. Wilson sketches admirably.

"Cyanide Processes," carefully read, will give the novice a working conception of this most important branch of metallurgy. The maturer expert will also find much that is suggestive and helpful.

Typographically, the book deserves equal praise. The half-tones and diagrams that elucidate the text are well chosen and clearly printed. The type is large and easy.

Compressed Air Plant for Mines. The Production, Transmission and Use of Compressed Air, With Special Reference to Mine Service. By Robert Peele, Professor of Mining in the School of Mines, Columbia University. First edition, 8 vo., 325 pages. Illustrated with plates, diagrams, half-tones and wood cuts. Price $3.00. John Wiley & Sons, 43 and 45 East 19th Street, New York, 1908.

The author, while laying no claim to presenting new facts, has gathered together a great deal that is both practical and serviceable concerning the use of compressed air. Every year, every week indeed, there are pages of interesting and often useful matter appearing in current technical journals. Much of this material is lost or forgotten in course of time. Mr. Peele has evidently followed his subject closely. He has extracted from the periodicals whatever has appealed to him as of sufficient importance. This material, together with his own intimate knowledge of modern practice, has enabled him to put together a book that is practical and instructive.

The first chapter traces the development of air compressors, and indicates the advantages of compressed air transmission of power over steam transmission. We will be pardoned for reproducing a few sentences from the first paragraph of the book, dealing with the history of the rock drill. "The first percussion rock drill, operating independently of gravity, was invented in 1849 by J. J. Couch, of Philadelphia. . . . Couch's machine, together with its immediate successors, such as the Fowle drill (1849-51) and the Cave (Paris, 1851), were steam driven, and therefore unsuitable for underground work. In 1852, the physicist Colladon proposed the use of compressed air for operating rock drills, in connection with the driving of the Mount Cenis tunnel. His idea was developed . . . between 1852 and 1860, and in 1861-62 an air-compressor plant was first used successfully at that tunnel. It was driven by water-power, and furnished air for ventilation as well as for the drills."

Straight-line, duplex, compound steam end, stage, direct and belt driven or geared compressors are described and compared in Chapter II. In Chapter III. the theory of air compression is outlined. Wet compressors, dry compressors, comparison of the two, compound or stage compressors, air inlet valves, delivery valves, performance of air compressors, air receivers, speed and pressure regulators, air compression at altitudes above sea level, air compression by direct action of falling water, are some of the subjects attacked in Part I.

Part II. is taken up with transmission and use of compressed air. The rules governing the economic conveyance of compressed air in pipes are enunciated and explained. Compressed-air engines are dealt with. In a clear and succinct manner freezing and its prevention are thoroughly discussed. The philosophy of reheating is the subject of an entire chapter. The four remaining chapters are devoted to rock drills, compressed-air pumps, pumping by direct action of compressed air, compressed-air haulage for mines.

Mr. Peele's volume is, in our opinion, exactly suited to the needs of the mine manager. This is tantamount to saying that it is a strong, well-balanced, usable book.

PERSONAL.

Professor M. B. Baker, School of Mining, Kingston, has returned from Lake Abitibi.

Mr. O. Simonis, of Henry Simonis & Co., London, Eng., spent September 21 and 22 in Toronto.

Mr. N. E. Isbell, a mining expert of Goldfield, Nev., has been making an examination of the Paymaster Gold Mine, Manitou Lake.

Prof. George R. Mickle, of the faculty of Applied Science, Toronto University, has accepted a position in the Ontario Bureau of Mines.

Mr. H. W. Scattergood, of Philadelphia, Pa., owner of the Little Master Gold Mine, Manitou Lake District, visited the property recently.

President Maurice Wendall, of the Northern Pyrites Company, has returned to New York after a visit of inspection to the company's property at Vermilion Lake, Ont.

EXCHANGES.

Engineering and Mining Journal, September 19, 1908. —Mr. Arthur R. Townsend writes on "Official Reports of Costs of Producing Copper." Remarking first upon the paucity of information as to capital, expenditure, etc., he dwells upon the diversity in arrangement of reports. "The cost per pound of copper, as has been noted above, is derived by dividing the total costs, less the income from other sources, by the total pounds of refined copper produced." Running over the costs of various Canadian and American companies, we note that copper was produced in 1906 at the following figures per ton.

	1906. $
Dominion Copper	0.174
Granby	0.133
Greene Con.	0.130
North Butte	0.07
Tennessee	0.107
Utah Con.	0.042

In the Lake Superior country costs per pound range from 24.62 cents to 6.76 cents.

The Iron and Coal Trades Review, Septemb r4, 1908. "The Coal Dust Question" is the title of a leading editorial in the Review of this date. Experiments have demonstrated that a dense cloud of coal dust is not required to initiate an explosion. One pound of dust per lineal foot is sufficient to supply material for a disaster. Four recent explosions have resulted from the use of permitted explosives. In all these cases some percentage of inflammable gas was present. Why was its presence not discovered by the firemen, whose duty it was to ascertain whether firedamp was or was not present? Defective eyesight, our contemporary states, may be one of the prime causes of this omission. A fireman should be able to detect easily a 3 per cent. firedamp cap. This requirement is in vogue in British Columbia.

CORRESPONDENCE.

To the Editor Canadian Mining Journal:

Dear Sir,—While I am pleased to note that Mr. Willmott has found leisure to reply to my criticism of his paper on "The Origin of Deposits of Pyrites," I, at the same time, regret that he has made no statement regarding the correctness of my criticism upon his paper on "The Iron Ore Deposits of Ontario." Instead of replying to this himself, he says that he will leave this task to Prof. Leith. For my own part, I do not consider it to be the part of a fearless combatant to send his friends into the firing line, and I am positive that Prof. Leith will not assume the work of answering me, because, from my intimate knowledge of him, I believe that he will gracefully accept the correction of a lapsus which admittedly has occurred. "Errare humanum est." Had Mr. Willmott's charity taken this adage into fuller consideration, he would not have been betrayed into a display of feeling which the occasion did not warrant. An old German saying would characterize such an outburst very tersely, but I shall not run the risk of falling into the very error that I have just been deploring.

In the following sentences Mr. Willmott has seen fit to admonish me: "Mr. Hille has done me the doubtful honor of reading my paper so carelessly as to be unacquainted with its contents." And again: "Criticisms of such papers are welcomed by the institute, and by the writers, and if more written ones were made the institute's journal would gain in value. Such criticism, however, should be of the facts given, or of the inferences drawn, and here Mr. Hille lamentably fails."

In reply to Mr. Willmott's first retort I may say that his claim that I had read his paper carelessly, and, in consequence, was unacquainted with its contents, can only have been adduced by him in the hope of weakening thereby my correction as regards his determinations of some of the Thunder Bay iron and pyrrhotite deposits, in which such gross errors apepared. This he emphasizes by my remarks: "Mr. Willmott attributes the origin of a large number of pyrite deposits to sedimentation, and refers for support to Beck, Kemp and others." I will now admit that I ought not to have shown so much charity, but that it would have been better had I expressed myself still more plainly and exposed the quoting of these observers in its right light. But I may here ask what earthly good is served by the citation of "current opinions," if they are not shared by either the authors or even by Mr. Willmott himself? They should merely have been cited for the purpose of drawing attention to the hypotheses of others which were incidentally enumerated by the later writers. Had they been discussing the same deposits which were treated of by Mr. Willmott, the case might have been different, but the citation of the theories of others concerning occurrences of pyrites, that are, perhaps, totally dissimilar, carries little, if any, weight. In our consideration of the origin of ore deposits, it is impossible to apply the same rule to each individual instance, although it might be reasonable, in considering certain periods, to admit the existence of a certain fundamental law, and then, if our personal experience is sufficiently wide in this respect, we are entitled to speak with more confidence in the matter, but if this is not the case, it is then dangerous to make too free comparisons between our own investigations and those of others. I imagine that the grounds for such confidence were somewhat deficient in the case before us, otherwise Mr. Willmott would have given us the benefit of a fuller explanation as to the origin of these solutions carrying sulphide of iron. Did the meteoric water dissolve pre-existing pyrite deposits, or did volcanic mineral springs containing such salts in solution overflow their vents, carrying them into the depressions of which he speaks. Moreover, would not deposits formed in this manner, although produced under widely different conditions, which presuppose phenomena that I might say are diametrically opposed to each other, both be classed as sedimentary deposits? Has Mr. Willmott given us a clue by which we may learn to which of these sedimentation processes he attributes the existence of the pyrites deposits? Only from one sentence we might be led to the conclusion that he believes meteoric waters to have been the vehicle which carried in the iron and sulphur salts, but again he says: "How the silica, iron and sulphur were dissolved and precipitated is not absolutely clear. Presumably, the iron was partly transported as a carbonate and partly as a sulphate." Here we observe what difficulties Mr Willmott has placed in his own way for considering the dissolution of these minerals by meteoric water, if that process was what he had in view. We find the same indecision not only in his paper, but also in a report to the Bureau of Mines for 1902, on the Michipicoten Iron

Region, in which he was a co-worker with Dr. Coleman. On page 162, a volcanic origin is indicated for these iron-bearing rocks, as expressed in the following words: "The source of the iron must be sought for perhaps in some of the basic eruptives of the series, if it is not looked on as a direct sediment, perhaps of a chemical nature, on the sea-bottom of the time." Also on page 170, under the heading, "Genesis of the Iron-bearing Rocks," a volcanic activity was spoken of, in the intervals of which the iron-bearing rocks, consisting of carbonate and sulphide of iron, were supposed to be laid down. It would doubtless have tendered more to the enlightenment of all parties concerned, if Mr. Willmott had informed us of the source from whence these solutions had been derived. He speaks of the existence of volcanoes at that period, which poured forth lava and ashes, doing so at repeated intervals, between which occurred the precipitation of various iron salts among those volcanic products. If it is implied that it was meteoric waters that brought these iron salts to those particular spots, I fail to comprehend where or how they managed to dissolve pre-existing pyrite deposits, because the overflowing lava and falling ashes and tuffs would have not only destroyed the permeability of the older rocks, but also destroyed their gossan, which might have accumulated upon them. Or, are we to understand that the solutions came from greater distances, overflowed these volcanic extravasations, and were relieved by them of their contents? If so, how can we account for the fact that oxygen did not act upon the iron in solution, precipitating it in the form of an hydro-ferric oxide long before it reached its supposed destination? Again, lava streams and ashes are usually understood to be mountain-building materials, and yet are we expected to believe that these solutions would flow uphill and nestle down into the rugged clefts and chasms such as are usually the features of the surface of lava streams? Yet further, I believe that it is almost universally conceded by geologists that the Keewatin rocks formed the first crust of our globe, by which is understood that first crust of which remnants have been preserved to us, and the rocks constituting this crust have been produced partly by the consolidation of the fluid, fiery constituents of the earth's earliest magma, and partly by a magma that became eruptive, broke through the former crust, and solidified thereon. We have further to take into consideration that the heat existing at that time, and radiating forth, from and through the cracks and fissures of these rocks must have been so intense that meteoric waters can have played only a very subordinate part in the deposition of minerals. We must, therefore, turn our attention to a much later period when the crust of our earth had attained such a thickness as to keep the subterranean heat confined to a far lower region.

Now the inference that must be drawn from the above considerations is that neither the pyrites nor the carbonate of iron deposits can be of Keewatin age, as claimed by Mr. Willmott. Of all the countries on our whole globe I do not think that there exists any locality in which the Keewatin rocks are so plainly observable as in the western part of our own province: further, there are very few portions of it which, in the course of my twenty years' residence here, I have not visited, and if it be not "contre etiquette" I might make an even stronger boast than that, that nature has favored me with a keen sense of observation, which has rarely played me false. Now I may say, that in all my experience I cannot recall one single case where an ore deposit found in the Keewatin could be termed a syngenetic product, but I have seen hundreds and hundreds of ore deposits in the same rocks which are epigenetic, that is, subsequently introduced. In support of his theory, Mr. Willmott quotes Van Hise, Leith, Coleman, Merriam and others, and he also compares and reproduces in the Bureau of Mines Report for 1902, pages 174 and 175, with two illustrations from Van Hise's report on the Vermillion Iron Range, that is to say on the Chandler Mine, with which he considers the Michipicoten to be analogous. Van Hise indeed does classify the Vermilion and Sudan formation under the head of Archaean, and consequently Mr. Willmott will classify them under the Keewatin. Now the greenstone in which the Chandler Mine rests is neither an Archaean, nor, what in my opinion is the same, a Keewatin rock, but it is an intrusive greenstone dyke, breaking through the Keewatin and the sedimentary rocks of the Sudan iron formation, and it is therefore a much younger rock. Further, the Vermilion iron-bearing rock formation is considered to be the same as that of the Mattawin and Hunter's Island; if so, then it is not of Keewatin age, but of the same age as the Amimikie. The fact that these iron-bearing rocks are found resting in the fissures of the Keewatin schists by no means implies that they are of the same age as the latter. The jaspers, ferruginous cherts, siderites, magnetites, martites and hematites of the Mattawin, Hunter's Island and elsewhere are identical in composition, structure and in origin with the Animikie, with this only difference, that, through local phenomena, the one is changed into magnetite and hematite, while the other has undergone less change, having partly retained the original structure, or having been changed only locally into hematite, and further the process of deposition was in the one case obstructed and in the other not. To explain this in other words: the plutonic springs, carrying the silica and iron in solution, overflowed their vents and deposited their contents unobstructedly into the depression of the Laurentian or Keewatin rocks, and these we recognize to-day as the Animikie: in the other case the flow of the solutions was partly obstructed by overlying rocks and they were compelled to seek an entrance into the larger and smaller fissures of the Keewatin. Of this fact we have ample field evidence, such as to leave the matter not in the slightest doubt.

In the foregoing argument I have endeavored to establish (1) that the iron ore deposits situated in the Keewatin rocks are not of Keewatin age, and (2), that consequently the Michipicoten pyrites, which Mr. Willmott thinks are so closely connected with the former, are also not of that age. He asks me to explain why this is the case.

If Mr. Willmott had studied what he calls the Keewatin iron ore deposits somewhat more closely, he would have discovered, (1) that, as I have explained above, they are not of Keewatin age, and (2), that they are not associated with pyrite deposits of the same age, and (3), that, whenever it so happens that sulphide of iron deposits occur in the neighborhood, the occurrence is accidental, because eruptions of greenstones, which were the originator of the pyrites, occurred all over the country, and, if a more precise definition is required as to the time at which this occurred, it must have been, as I have formerly stated, in post-Animikie times.

Mr. Willmott's own observation, that the Michipicoten iron-bearing rocks occurred neither in the Keewatin schists, nor in the Laurentian granites, nor in the Lower Huronian conglomerates, which border that strip for a distance of 60 miles in length and in varying width, supplies the very explanation that he desires,

namely, that the eruptions of younger rocks occurred along a line of weakness where the older rocks were cut out. Similar examples might be quoted from many localities in our western districts, but also just as many in which we find the pyrite deposits in the enlarged planes of the Keewatin schists, produced by laccolithic intrusion of basic rocks.

As an explanation of the fact that these deposits contain not only sulphide, but also a carbonate of iron, it may be assumed that in the earliest history of our globe magmatic waters, fumaroles and other volcanic emanations contained iron, not only in the form of a sulphide but also as a carbonate, and that a considerable portion that might not have been carbonated at the lower depths, became so after ascending to the surface, because in those early periods the outer atmosphere must have been saturated, or at least impregnated with a large percentage of carbon dioxide. Proof is furnished by the Mattawin, Hunter's Island, Steep Rock Lake, Animikie and all other Lake Superior iron deposits, that a large, if not the largest, portion of the iron ores of that age were laid down as carbonates, and therefore there is nothing so very astounding in the fact that the Michipicoten pyrites occur associated with siderite.

Before concluding, I wish to say that Mr. Willmott is hardly justified in complaining of my remarks regarding the statements, made in his first paper, concerning the Schreiber pyrrhotite deposits. He wrote: "Near Schreiber . . . . is a pyrite, of a different character, ... mixed considerably with pyrrhotite and associated with a diabase." It will have been noticed that Mr. Willmott mentioned this deposit among other "iron disulphide" deposits, and further he calls it a pyrite in which a certain amount of pyrrhotite is mixed with it. The fact that he associates this deposit with a diabas will not be taken to signify that he did not intend to class this deposit as a pyrite produced by sedimentation; otherwise he would have given a clearer definition of its origin. He has, however, fallen into the same error as regards the Schreiber deposit as he fell into in the case of the Kaministiquia deposit. Both are of the same nature; both are true pyrrhotites, produced by magmatic differentiation, from rocks which are, in neither case, diabas, but altered diorites. Moreover, there are in either locality at least five or six such deposits.

Your truly,

F. HILLE, M.E.

Port Arthur, Ont., Sept. 10, 1908.

Canadian Mining Journal:

Dear Sir,—Your correspondent takes exception to a statement said to be from the Geological Records concerning the origin of a fire in the coal seams of Glace Bay more than a century ago, and states that no one in Cape Breton ever heard this version of the ocurrence. He further states that Brown's History makes no mention of it. Whether true or not, the most commonly accepted theory of the fire which occurred at Burnt Head is that it was fired by the French, as it was being worked by the English. It was defended by a blockhouse or fort garrisoned by fifty men, and was frequently attacked by roving bands of French and Indians. If your correspondent will turn to page 50 of Brown's History, which he quotes, he will read quotations from "History of Cape Breton" by M. Pichon, at that time Secretary to the Governor of Louisburg, in which he refers to a party of officers being sent by the Governor of Louisburg in the spring of 1752 to survey the coasts and gather statistical information. Pichon refers to this mine and fort, and states that the pit took fire in 1752, which is the date of their visit, and that both pit and fort were destroyed, but he does not mention the origin of the fire. Traces of this fort and the ravages of the fire in the cliffs are still plainly visible at a point still known as Burnt Head, where the Dominion Coal Company is working the Hub seam of coal.

Another story is that it was fired a second time and at a much later date than above recorded. This story is that during the lease of all the coal fields of Cape Breton to the General Mining Association some officers of the company, whose duty it was to patrol the coast to prevent poaching, discovered some pits at Burnt Head were being worked by coal poachers, and in order to stop this the officers exploded powder in the mouth of the pits or slopes in order to destroy the works and prevent any further operations, thus deliberately setting fire to the seam. It could hardly be looked upon as a reflection on the brave Frenchmen who were then constantly at war with the English, if they did destroy their property.

Yours truly,

C. M. ODELL.

ABITIBI LAKE DISTRICT.

Editor The Canadian Mining Journal:

Dear Sir,—Having just returned from Abitibi Lake, where I have been engaged in making a geological map of that area for the Bureau of Mines of Ontario, I am writing you a few impressions that may be of interest to some of your readers.

In 1900 the writer visited that area as geologist to an exploration party for the Bureau of Mines, and it is a great contrast to visit the same area now, only eight years later. At that time it was a week's journey by canoes and portages over the "Quinze" route, which forms the head waters of the Ottawa River. The starting point then was Temiskaming Station on the C. P. R. Now one can reach the same area in one day from the end of steel at McDougal's Chute on the Black River. Here a line of steamboats ply between the Chutes and points on Abitibi Lake, so that this area, which seemed so far away only eight years ago, is now at our very door.

Three districts in New Ontario have recently attracted attention as possible gold fields, viz., Larder Lake, Night Hawk Lake and Abitibi Lake. Gold was reported in Bureau of Mines reports in 1900, but the Abitibi Lake area did not attract much attention till 1907, when a pronounced rush took place, as evidenced by the promiscuous staking that was done there. If any honest, genuine mining man wishes to see the length to which men will go in a mining rush, where inspection is not operative, he has but to visit Abitibi Lake. Making all possible allowance for ignorance as to what is "valuable mineral in place," or even what is a possible economic occurrence, it is still painfully clear that a large part, yes, a majority of rush prospectors think nothing of the perjury of which they are guilty. One has only to see some of these disgraceful stakings to affirm that. Whether the present system of inspection as practised is best or not, certainly the underlying principle of inspection, viz., "discovery," must be insisted upon, to preserve for proper purposes those areas which are not nor ever can become mining lands.

This last point brings me to consider what I believe to be the future of the Abitibi District. Gold has been found at Abitibi Lake, it is true, but it can hardly be called a gold field. Three properties have been prospected honestly and well. The most important work has been done by Mosure Bros., on Shaft Island, numbered on the Government mays as 173. Here a shaft about 73 feet has been sunk on a quartz vein, varying in width from 4 inches to 4 feet. Free gold can be seen in selected specimens, and no doubt much of the ore in which no free gold can be seen assays well. The body, however, is not large, and unless the values run high it would be a difficult proposition.

The second property of importance is the Big Pete Mining Company's location on the east shore of the Lower Lake Abitibi. This company has a large vein of sugary quartz, impregnated with pyrrhotite, pyrite, chalcopyrite, graphite, etc. The manager was setting a diamond drill, which is to thoroughly test the veins at depth, and the results of these tests will be awaited with interest. A third party were working under a Mr. Reese, of Detroit, developing a quartz vein in diabose on the big island No. 149, just at the north end of the narrows which connect the two parts of Abitibi Lake. This work is still going on, but at the time of the writer's visit no free gold could be seen. It does not look, therefore, as though Abitibi Lake is to become famous as a mining camp.

As mentioned above, I believe the future of this area lies in agriculture. A generally mistaken impression seems to have been formed by the public in older Ontario, viz., that the portion of Ontario lying north of the C. P. R. main line is practically a rocky waste, with possibilities only as a mining district. This is decidedly incorrect, and a very few years will justify the confidence the Legislature of Ontario placed in that north land when it undertook the construction of the T. & N. O. Railway as a public utility.

Beginning at the town of New Liskeard, just north of Cobalt, is an area of roughly one million acres of splendid sandy clay loam, just sufficiently rolling for good drainage. It is well watered, and will be well served by the T. & N. O. Railway and the G. T. P. Railway when completed. I brought out timothy and ripe oats and barley pulled the second week in August. The samples are excellent, and the hay especially good. These were grown in the small clearings around the railway "caches" and horse-stables. Moreover, the engineers of the G. T. P. Railway have gardens, in which they have successfully grown peas, beans, carrots, onions, beets, radishes, lettuce, celery, cabbage, potatoes, in fact every table vegetable was grown by one or another. Mr. E. P. Goodwin, the divisional engineer, even ripened tomatoes on his vines.

This information goes to show clearly that once the country is cleared and cultivated, it will offer a splendid agricultural district. The land is timbered entirely with pulpwood, and will therefore be easily cleared, as a ready sale for the pulpwood can be had at the railway once it is operate.

M. B. BAKER, B.A., B.Sc.
School of Mining, Kingston.

Editor The Canadian Mining Journal:

Dear Sir,—In your edition of September 1, 1908, you give, on page 437, a list of the operating mining companies of Nova Scotia.

Your correspondent has made one important omission in failing to mention the Oldham Sterling Gold Company, Limited, operating at Oldham, in Halifax County. This mine has been in continuous operation for six years, and is mining successfully at a depth of 1,250 feet. The mine is easily the second largest producer in the province, its production being exceeded only by that of the Boston Richardson, at Isaac's Harbor.

Trusting that you will be kind enough to make the correction, I am,

Very truly yours,
C. V. BRENNAN.

Oldham, Nova Scotia, Sept. 18, 1908.

SPECIAL CORRESPONDENCE

Glace Bay, Sept. 17.—There has been a little slackening off in the coal trade in Cape Breton during September as compared with the rest of this summer and with the same period last year. Last year it will be remembered the opening of navigation was unusually late, and the whole shipping season was marked by a scarcity of labor and a falling off in the effectiveness of the working force generally. This phenomenon was not confined to Cape Breton, but was pretty generally remarked in all English speaking countries. The result was that large outputs were requisite in September and October in order to fill the St. Lawrence requirements before the ice formed again. This year conditions have been very different. Navigation opened at least six weeks earlier than in 1907, and good outputs, exceptional outputs indeed, have been obtained all through the summer. Most of the Cape Breton companies are ahead on their shipping programme. The Dominion Coal Co., for instance, is 300,000 tons ahead of last year at this time. This is partly due to the favorable season, but more to the fact that labor has been more plentiful than of late years, and to the men having worked more steadily. We are feeling the reflex of the financial depression that has affected this continent since last winter, and the probabilities are that the coal trade will be quiet until next spring.

The miners of Cape Breton, more particularly those employed by the Dominion Coal Co., are to a certain extent to be blamed for the slackness that is manifesting itself. The actual capacity of the Dominion Coal Company's mines is very little greater this year than it was last, but during the whole of last summer, as we have said, owing to the disinclination of men to work, the outputs were restricted, and the Coal Company found it difficult to fulfil their contract requirements. This season they decided not to incur such a risk again, and they estimated their outputs very conservatively, making contracts accordingly. It will also be remembered that a little later than this time last year the Dominion Coal Co. offered their workmen the option of a three years' contract on the fairest terms, giving as their reason for so doing the importance of having settled conditions and long term contracts for the successful prosecution of their business. The Coal Company pointed out that these terms were offered in the face of a falling market, and a probable industrial slump. The men afterwards accepted under a Conciliation Board less favorable terms than were originally offered them, but the good faith and sincerity of the Company's offer is now evidenced by the fulfilment of the forecast of the management.

The supply and price of pit timber is a question that is every

year becoming more serious to the operators of coal mines in this Province. Mining at greater depths, the increased amount of long-wall extraction in the thinner seams, and the generally greater amount of roof that must be supported as mines go to the deep, and as the old pillars are withdrawn, are all matters that tend to increase the demand for pit timber. In common with the rest of Eastern Canada, the timber resources of Cape Breton and Nova Scotia have been shamefully squandered and wasted. The combined effects of insect pests, forest fires and reckless and unscientific lumbering operations have made good and suitable pit timber a difficult thing to obtain in a country where it should be a staple product. In Pennsylvania and other States of the Union coal operators have found it has paid them to systematically raise their own pit timber. About seven years growth under suitable conditions will produce timber that is very suitable for pit props. In the Black Forest of Germany, in the Vosges Mountains of Frances, in Sweden and Denmark, forestry has been raised to a fine art. Land suitably planted is found to return as much from timber as can be obtained from cultivated farm lands. It is an interesting sight to walk through the groves of one of the Imperial plantations in the Black Forest, and to see the straight clean timber, in symmetrical lines, every stick of which will be felled at an appointed date, to be succeeded by fresh saplings. It is only such scientific methods as these which have enabled the Baltic Provinces to supply the insatiable demands of the British coal mines year after year, and one has only to view the floating acres of pit timber in the East Coast ports of England to realize how profitable such a trade must be. We were recently told by a gentleman who buys large quantities of mine timber that there were large areas of young larch in the province, which would make excellent pit timber, if properly thinned out and cared for, but which in all probability will grow up useless and stunted for lack of care, or will some day be licked up in a forest fire. Scientific afforestration is a crying need of this continent, and it is needed in Cape Breton. That this country can produce large timber, or at least commercial timber, is evidenced by the large stumps that one notices in the woods, and the lusty growth of the young timber. Much of Cape Breton is sterile and stony country, and utterly unsuitable for farming, but under proper laws and supervision it could doubtless be made to raise profitable growths of timber.

The Draeger apparatus of the Dominion Coal Company received its baptism of fire on the 10th inst. at Sydney Mines, and the "boys" from the Rescue Station returned covered with grime and glory. They returned from Sydney Mines in the evening of the 11th after having had probably the most strenuous double shift in their lives. As they lined up in front of Sydney postoffice waiting for the Glace Bay car, they were about as tired looking a crowd of men as one would wish to see, and no doubt they slept well when they reached home. One could hardly imagine a more exacting task than these men had performed, and after their work at Sydney No. 1 they may be classed as past masters in the mysteries of oxygen apparatus. They did their work in a very effective manner, and made no fuss about it, as is the wont of miners when asked to render assistance. All the same the showing of the Glace Bay men was most gratifying, proving as it did their own effectiveness should a like emergency arise here, and the effectiveness of the Rescue Station equipment. This latter will shortly be augmented by a "Dr. Brat" automatic oxygen reviving apparatus, a most ingenious arranement, which will induce artificial breathing, and will revive a person who is "gassed" more quickly than anything else. This arrangement can also be used to resuscitate unconscious persons on whom it is not possible to use the ordinary Slyvester method of inducing artificial respiration, by reason perhaps of a broken arm or fractured ribs or similar disablement. The coal company are also purchasing a stretcher, fitted with a similar arrangement to that described, on which it will be possible to strap securely an injured or unconscious person and supply him with oxygen. The stretcher is fitted with a grooved wheel which can be run along the rail, and it is thus possible for a rescurer wearing a breathing apparatus to drag an injured person through after-damp or other noxious gases, and keep him alive until he can reach the outer air.

QUEBEC.

New Asbestos Industry for Quebec.—The D'Israeli Asbestos Company, which was organized recently to develop their property at D'Israeli, Quebec, are actively pushing to completion their railroad which runs from D'Israeli to the quarries, a distance of some three miles. The asbestos ore found on the propert yof the company is of exceptionally high grade quality, and from an examination of the engineer's report the product from this mine can be mined and milled cheaply and conveniently.

It is expected that the plant, which will be of a 250-tons capacity, will be constructed and in operation about December 1, next.

ONTARIO.

Cobalt.

La Rose.—The preliminary statement of production and earnings for the months of June, July and August, shows a net profit of:—

June	$82,867.55
July	127,329.00
August	108,603.00
	$318,799.55

The statement for the August production was as follows:—

	Tons.	Silver Contents. Ounces.	Net Value.
Shipments	645	278,570	$124,656
On hand August 31	40	78,000	40,000
Production	645	356,570	163,406
Less on hand July 31	57.94	79,739	38,803
	627.06	276,831	$124,603
Estimated expenses			16,000
Net profit for August			$108,603

As practically no ore has been stoped from the mine, there is no reason why this production should not be maintained, or materially increased.

White-Hargreaves.—The suit brought by the Attorney-General of Ontario to set aside the leases granted to the White Silver Mining Co. and E. C. Hargreaves on three claims located in the proven producing area of the Cobalt District, has been settled. This settlement provides that E. R. C. Clarkson is to hold the three claims as trustee for E. C. Hargreaves, Wm. F. White, Jas. McKay and Jas. C. McMillan. The Ontario Government is to receive a royalty of 25 per cent. on the gross output of the mine. These properties are exceedingly well located and the development work, which has been suspended since the spring of 1906 owing to litigation, should result in proving some valuable veins.

Watts (King Edward). The new concentrating mill at the King Edward will be in operation next week. It has been decided to gradually increase the capacity to 200 tons per day. There are over 15,000 tons of milling rock on the dump. The underground developments are very favorable. A very rich vein ten inches wide was recently discovered and a large tonnage of milling ore is blocked out.

Coleman Cobalt (Amalgamated).—A very promising vein of calcite and silver has been found in the Coleman Cobalt lot, one

of the properties of the Amalgamated Cobalt Mines Co. This property is under lease to a syndicate headed by S. D. Madden.

Coniagas.—A new battery of ten stamps is in successful operation at the Coniagas mill. Twenty more stamps are being installed, which, when completed, will give the mill a capacity of 100 tons a day. As the output of the mine has been limited to the capacity of the mill, a large increase in output will result.

Temiskaming.—The new plant, which will be one of the most complete in Cobalt, is well under way. The plant will consist of a 20-drill Sullivan compressor, high-pressure boilers and a new hoist. A three-compartment shaft is being sunk to a depth of 250 feet to connect with the present workings. A 60-ft. steel head frame and a shaft house will be built. In an upraise from the 200-foot level the ore body has widened out from 6 inches to 2 feet of very rich ore.

Crown Reserve.—The exceedingly favorable development of the Crown Reserve vein, which is the widest and richest in the camp, is still the chief topic of interest in Cobalt. It is impossible to arrive at a fair estimate of the values existing between the open cut from which the first shipments were made, and the prospect cross cut from the working shaft. It is, however, safe to say that no vein in the Cobalt Camp can show an ore body extending for an equal distance of anything like such values. An open cut has been made 45 feet deep and 50 feet long at the west boundary of the property adjoining the Silver Leaf, and a winze sunk a depth of 40 feet from the bottom of the cut. The vein is persistent for the entire depth, averages over 5,000 ounces silver, and is from 12 to 30 inches wide. The wall rock is also heavily impregnated with native silver. A working shaft has been sunk at a distance of 200 feet from the west boundary line to a depth of 118 feet and a cross cut driven in 80 feet from the shaft at the 100 foot level. At a distance of 25 feet from the shaft the main vein was encountered and a drift started west towards the winze. This drift is now in 35 feet, all in high-grade ore, the vein averaging 10 to 12 inches in width. This indicates that the vein is continuous from the Silver Leaf line to the working shaft, practically blocking out a body of very high-grade ore 200 feet in length. The Silver Leaf shaft, which is also near the boundary line of the two properties, is producing high-grade ore at a depth of 200 feet. The new plant is practically completed. A six-drill compressor, boilers, electric light plant, etc., have been installed and a 60-foot head frame completed. An extensive plan of development has been inaugurated. At the 100-foot level the cross cut will be driven in to the north boundary line, a distance of 100 feet. From this point a prospect tunnel will be run to the east the full length of the property, approximately 800 feet, and at intervals of 500 feet, prospect cross cuts will be run. It is expected that the No. 7 vein of the Kerr Lake Mine will be encountered in the prospect tunnel about 200 feet from the cross cut. Ore valued at $300,000 has been shipped. There is approximately $200,000 worth of high-grade and $25,000 worth of unsorted ore in the ore house. It is estimated that over $150,000 worth of ore is left standing in the mine.

Rochester.—A party of directors of the Rochester Cobalt Mining Company visited this property last week. It was decided to increase the working force and sink the main shaft to a depth of 200 feet. The improved outlook at the Badger Mine, where high-grade ore is being taken from the main shaft, offers every encouragement that the Rochester vein will show paying values at depth. The veins on both properties are in a contact between Keewatin and diabase.

Davis Silver Cobalt.—Two 20-acre claims of this company, which adjoin the Badger Shamrock, and Fisher-Eplett, on the north, have been leased to the Shamrock Company. A discovery of two parallel veins of calcite and cobalt with small silver values has been made on one of the Davis properties at Giroux Lake. Twenty men are now employed trenching and a shaft is to be sunk to a depth of 100 feet.

Montreal River District.—The important discoveries which have recently been made in the vicinity of Bloom, Miller, Everett, Le Roy and Gow Ganda lakes, have resulted in a great influx of prospectors and the blanketing of large areas of more or less promising territory. The situation regarding the proper location on the map and the issuing of applications and certificates of record is fast becoming so complicated that there is grave danger of endless litigation. This territory is unsurveyed and the staff of inspectors and assistants is totally inadequate to handle the situation. Twenty-seven claims were recorded in one day at the office of the recorder at Elk Lake. As no surveys have been made the recording office is forced to take the description of the licensee, with the result that a large number of the claims recorded are more or less improperly and incorrectly described and placed on the recorder's map. There is a strong feeling in this section that the force of inspectors should be greatly increased and the new territory, which is undoubtedly exceedingly promising, should be surveyed at the earliest possible moment.

Temiskaming and Hudson Bay.—In running a prospecting tunnel at the 100 foot level, a vein of calcite and native silver, five inches in width, was found. It will run 6,000 ounces or more. This vein is 20 feet from the northern boundary of the Trethewey and will run right into that property. The Trethewey will catch the Meyer vein also. This is being driven on now by the Nipissing Co. at the 80-foot level. Another 20 feet will bring the drift up to the Trethewey line. The values are high in this vein.

O'Brien.—At the 175-foot level in the No. 2 shaft, a cross cut being run southwest cut a five-inch vein of ore that will run 2,800 ounces. This is not more than 40 feet from the Chambers-Ferland line and running into it.

BRITISH COLUMBIA.

Rossland.

The ore body on the 1,650-foot level of the Le Roi Mine is showing up well under development. The shoot at this point varies from 15 to 20 feet in width and carries good values. The ore body on the 1,450 feet level looks promising but more development will be necessary to prove this ledge. The Le Roi profits for August were of a satisfactory character.

The members of the Canadian Mining Institute and their distinguished guests looked over the city and the adjacent mines and were entertained by a banquet here. The local mining men and citizens did all in their power to extend that hospitality to the visitors which is a thing apart from the hospitality shown by other districts.

A gallows frame is being built on the Idaho section of the Centre Star property and the shaft now doubt 35 feet on the ledge, will be sunk to a greater depth.

The lessees of the Blue Bird have shipped another car of hand-picked ore to Trail smelter, from which good returns are anticipated.

Active work continues on the various small properties and shipments will be made from several in the near future.

Boundary.

The party of foreign mining men and the members of the Canadian Mining Institute were greeted with a 21-gun salute from Granby Hill when they arrived in Phoenix on the 18th. The party was shown through the premier copper mines by A. B. W. Hodges, local manager, G. W. Wooster, treasurer, and other Granby officials. They entered the mine by the main outlet, the Victoria shaft, with its complete hoisting, crushing and shipping facilities. The compressor plant was viewed and later the party was taken into the depths of the hill on the underground electric railway, through No. 3 tunnel. The tourists were treated to an innovation by the management in one of the large stopes. This prodigious cave, 125 feet high and about the same distance wide, was viewed by the party from the brink of the

tunnel level. Away in a distant region of the stope Mephistopheles was seen rejoicing in a wealth of brilliant fire, the scene ending in a burst of fireworks. After a luncheon at the Granby Hotel the party left Phoenix for the Grand Forks smelter.

The coke situation in the Boundary is getting into much better shape and the Granby is once more running seven furnaces. As a consequence of this activity at the smelter the Granby shipments have increased in the last two weeks from 13,741 tons to 25,147 tons for the week ending Sept. 19th. The B. C. Copper Co. was not affected to any extent by the coke shortage, as their supply of coke is obtained from the International Coal & Coke Co., Coleman, Alta., and they have been able to maintain steady shipments; and, in fact, to increase their tonnage from the Oro Denoro property.

Work has been resumed on the Brooklyn and Rawhide mines of the Dominion Copper Co., but up to this date the smelter has not been blown in. The opinion has been expressed that with the management that is necessary in the Boundary for successful mining and smelting and with up-to-date mining and transportation facilities the Dominion Copper Co. could be made to pay as well as other Boundary concerns. The ore in the Phoenix mines of this company is in some portions even richer than the Granby ore and it looks as though in the end the Dominion Copper Co. could be made to pay good profits.

The Greenwood Tunnel scheme is still heard from occasionally. The promoters state that work will be commenced shortly; they also report that an application has been made for tramway rights, to be used in connection with the bore. At present the predominant idea seems to be the cutting of rich ledges that may or may not lie in the path of the proposed adit. The tunnel as a commercial enterprise is $3,000,000 distant at this stage and a little nebulous.

A company is being formed to take over and develop the Greyhound group, near the B. C. Copper Co. mines in Deadwood camp. This is a promising group and those who know the property will be glad to see work once more going ahead there.

The B. C. Copper Co. is negotiating for the purchase of the Molly Pritchard and Athelstan Fraction, in Wellington district. They have secured an option on these claims from the owners and engineers of the company have been over the ground and examined the property. The ore on these claims is an arsenical iron ore carrying paying values in gold and silver.

The B. C. Copper Co. is securing property in the different camps, making sure of a steady ore supply for the future. The company already controls several meritorious mines just across the line in the State of Washington and has more recently bonded the Acme, near Kettle Falls, Wash., for $50,000.

The Dykehead claim, near the Fife lime quarry of the Consolidated Co., has been bonded for $50,000 and will be developed all winter. A 100-foot development tunnel is to be driven on the Bruce, Midway.

The returns from the last car of 21 tons of ore that was shipped from the Sally have been received. After freight and treatment charges, which were heavy owing to the long haul, were deducted (they amounted to $80 per ton) the carload shipment returned the company $3,175.

The Snowshoe continues to ship over 400 tons of fluxing ore per day to the Trail smelter.

Nelson.

There is much activity exhibited at Salmo. A telephone system is to be put into the mines on the surrounding hills. A deal is on with Minneapolis capital for the Relief Mine. The Arlington Mine, controlled by English capital, is producing ore steadily. The average value of the ore extracted is $75 per ton. The ore body is a blanket lead and runs from two inches to a foot in width.

A rich strike is reported from the Nugget. A ledge has been exposed carrying rich values in gold.

The Silver King at Nelson is shipping to the Trail smelter. At the Fisher Maiden, high-grade ore is being sacked and a shipment will be made soon.

The North Star still continues to produce over 150 tons per week despite the gloomy reports that have been sent out from time to time that there was no more ore in the mine.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—Serious trouble is brewing in the ranks of the Provincial Workmen's Association. Delegates to the Ground Council have decided by a vote of 48 to 27 not to amalgamate with the United Mine Workers of America.

Sydney, Sept. 25.—The Domnion Iron and Steel Company has received an order for 9,000 tons of 80-pound steel rails for the Southern Pine Joint Railway, to be delivered by steamer direct to Couriche, via Suez Canal, India. The company will commence to roll this order October 13th. The order was secured in competition with the world, and had to be approved by the Viceroy of India.

ONTARIO.

Cobalt.—(Special to The Canadian Mining Journal).—The recent discovery near the north boundary of the Trethewey Mine is one of great importance. The discovery was made under unusual circumstances. The Temiskaming & Hudson Bay Company has ceased driving on what appeared to be a worthless stringer approaching so closely to the Trethewey line that further operations seemed inadvisable. The Trethewey Company, after having conducted extensive surface operations at the north end of their property, entered into an agreement with their neighbors to have the underground work continued on the Trethewey ground at the 100 foot level with the object of gaining information at depth with a minimum of cost to the Trethewey Company, and with advantage to the Temiskaming & Hudson Bay Company, which would gain information that otherwise it might not seek. The result is that in following the small stringer towards the Trethewey line a large and rich vein intersecting the line between the properties and trending about northeast and southwest, has been encountered. Should the present strike of the new vein continue, it will traverse practically the centre of the Trethewey property, and add enormously to its value. This company has recently installed a crushing and jigging plant, which is working very satisfactorily. The result will be that instead of shipping 4 or 5 carloads per month of various grades, the shipments will be reduced to one or two carloads of high-grade ore, thus saving freight and treatment charges on about three fifths of the mine product. This saving will amount to about $2,000 per month, besides which the price to be realized for the ore shipped will be considerably enhanced, as high grade ores meet with better terms from the Smelters than ores of lower grade.

Cobalt, Sept. 19. It is rumored that Nipissing and La Rose are to combine in the erection of a concentrator to treat the output of both mines. Such a move would result in a saving of $10 to $13 in freight on the heavy low grade ore shipments from La Rose.

Sault Ste. Marie.—Specimens, rich in gold, have been brought into town from the Golden Reed Mine at Michipicoten.

ALBERTA.

Lethbridge.—The Royal Collieries Company, Ltd., of which H. N. Galer, of Spokane, is president, expects to attain an output of 300 tons per day by the 15th of November. The seam on which the company is working is 4 feet 3 inches thick, and is reported absolutely clean. Marketing will present no difficulty.

BRITISH COLUMBIA.

Fernie.—On the evening of September 14th the Canadian Mining Institute excursionists returned to Fernie after inspecting the Coal Creek collieries. The evening was spent at the offices of the Crows' Nest Pass Coal Company. The smoker given by the company was signally successful. President G. G. S. Lindsay, occupied the chair. The entertainment was essentially Scotch. Reels, sword dances, bagpipes, etc., were the principal ingredients of the programme. The special train left at midnight for the west. The excursionists were met at Coleman by Manager J. D. Hurd and Superintendent Charles Sinister, of the C. N. P. Coal Company, who accompanied them as far as Fernie.

Rossland, Sept. 16.—Delayed by the burning of a railway bridge, the Canadian Mining Institute was a day late in reaching Rossland. The special train is expected to-day, however. The visitors will be given a banquet at the Hotel Allen, and will leave at midnight for Trail. During the day they will inspect the mines near the city.

Phoenix.—A group of Boundary proprietors, including the Molly Pritchard and Athelstan fraction, the Jackpot, the Buttercup, all about three miles from Phoenix, are said to have been acquired by the British Columbia Copper Company.

Rossland.—Le Roi Mine is looking well at 1,650-foot level. The ore shoot is from 15 to 20 feet wide. On the 1,450-foot level the ore shoot is showing promise. The company's profits for August were above the average, and September will probably exceed August.

Nelson, Sept. 20.—Shipments of ore for the week ending September 19th were 3,000 tons greater than at any period of 1908, and were within a few hundred tons of breaking all records. Five thousand tons of zinc ore have been shipped lately to American smelters.

YUKON.

Dawson City.—An innovation in the way of electric elevators is to be introduced by Boyd & Jepperson, who operate on 82 below, Sulphur Creek. By sinking an incline shaft, in which the bucket line will be operated, the necessity of handling the overburden is done away with. The hydraulicing of the pay will be done with a pulsometer and hot water. It will be possible to maintain a clean roof of even depth, and thus the handling of waste will be reduced to a minimum.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The Conciliation Board of the Federated Districts of England and North Wales have reduced miners' wages 5 per cent.

The Headquarters of the Institution of Mining Engineers has been transferred from Newcastle-on-Tyne to London.

A new colliery syndicate is being organized to acquire the minerals of Pentremawr and the southern portion of Bettwa Mountain, in Wales. From a quarter to half a million pounds will be invested, and the pit put down will, it is said, be the deepest in Wales.

RUSSIA.

The Russian platinum industry is suffering by reason of the fall in prices and a decrease in the demand owing to the substitution of other metals. The Government is being asked to come to the assistance of the producers.

The Russian copper industry is practically under the control of a trust known as the Mied Association, organized last January. Out of 1,100,000 poods probable production of copper, 90 per cent. is in the hands of the association.

NORWAY.

An attempt is being made to provide for compulsory arbitration, a measure introducing it being drafted for submission at the next session of the Storthing.

GERMANY.

Messrs. Benzenberg & Hengstenberg are erecting a large briquette works at Ruhr Harbor. Petroleum pitch will be used as a binding medium for the working up of lean coal slack.

The Wurttemburg Government has issued a warning to investors against wild-cat coal-mining enterprises.

AUSTRALASIA.

A recent discovery of tin made by Chinese at the Gulf, Emmavitle, New South Wales, is declared to be the richest ever made in the locality. The lode is 15 feet long by 5 feet wide, so far as uncovered, and yields a ton of tin per day.

The Elmore concentrating process, which was tried some time since for the refractory copper ores of Fort Burke, Cobar, New South Wales, but discontinued as unsuccessful, is being given another trial there, under the supervision of one of the patentees.

The Victoria State Government is asking for an appropriation £100,000 for the encouragement of mining. Of this, £75,000 will be devoted to the direct encouragement of gold and coal mining.

A Government party sent to Derby, Western Australia, to investigate the iron deposits on an island near the coast report immense deposits in the cliffs rising 500 feet from the sea on an island in Yarnpi Sound. Preliminary assays show the ore to contain 79 per cent. iron.

SOUTH AFRICA.

The prospects of the tin mining industry of the Transvaal have improved greatly during the last few months. In the Bushveld about £43,000 worth of ore has been produced in the last six months, and many additions made to producing mines.

The wages of white miners in Rhodesia have been reduced about 20 per cent.

The Transvaal gold output for July was 584,455 oz., valued at £2,482,608, an increase of 9,482 oz. over the previous mouth. This constitutes a new record, being the largest amount of gold produced in any one month in the Transvaal.

UNITED STATES.

A new mining camp has been established 14 miles southeast of Cima, San Bernardino County, Cal., named Gold Valley, where a tent city has sprung up in a few weeks. A number of veins have been discovered, and though they are small, the ore is of high grade.

Colorado mining men have been holding a two days' session in the Denver Chamber of Commerce. Prominent among the

subjects discussed were the need of legislation for the punishment of fraudulent and untrue statements in mining properties, and the means requisite to bringing the mining advantages of the State before the world.

A commission, comprising the head of the Explosives Commission of Britain, the heads of the German and Belgian Mining Commissions, and Dr. J. A. Holmes, of the U. S. Geological Survey, have been in consultation with Indiana mining officials at Terre Haute, as to the prevention of mining disasters, as a result of the Hemenway bill appropriating $150,000 to cover the cost of investigating mining conditions.

All the mines of the Boston & Montana Company at Butte, Montana, have resumed operations after a shut-down of three months.

PHILIPPINE ISLANDS.

The Government coal mine on Batan is being opened, and it is expected that shipments of 2,500 tons per month can be made beginning with October. The Insular Coal Company is pushing work on its mine at Camansi, and will build a railroad to the port of Danao.

The total shipments for the week were 1,199,770 pounds, or 600 tons. Total shipments from January 1 to date are 31,963,813 pounds, or 15,982 tons. The total shipments for the year 1907 were 28,081,010 pounds, or 14,040 tons, valued at $6,000,000. In 1904 the camp produced 158 tons, valued at $130,217; in 1905, 2,144 tons, valued at $1,473,196; in 1906, 5,129 tons, valued at $3,900,000.

The output of the collieries of the Crow's Nest Pass Coal Company for the week ended September 18th was 19,284 tons, or a daily average of 3,205 tons. For the corresponding week of last year the output was 21,905 tons, a daily average of 3,651 tons.

The output of the Crow's Nest Pass Coal Company collieries for the week ending September 25th was 16,643 tons, a daily average of 2,774 tons. The Michel mines were idle Monday, pay day. For the week ending September 27, 1907, the output was 19,439 tons, a daily average of 3,240 tons. For the same week in 1906 the output was 4,856 tons, daily average 809 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, Sept. 12.—The ore shipments from the various mines and the receipts at the smetlers of the districts of Southeastern British Columbia for the past week and year to date were as follows:—

Managing Director's Report.

Trail, B.C., August 15th, 1908.

To the Directors of The Consolidated Mining and Smelting Company of Canada, Limited:

Gentlemen,—I beg to submit the results of the Consolidated Company's operations for the year ending June 30th, 1908, including Balance Sheet, Profit and Loss Account, Production, and General Report.

(*To be continued.*)

DIVIDEND NO. 12, KERR LAKE MINING COMPANY, OF COBALT, ONT.

New York, Sept. 8th, 1908.

The Board of Directors have this date declared a regular quarterly dividend of Three Per cent. (3 p.c.) upon the capital stock of the company, payable September 19th, 1908, to all stockholders on record at close of business September 15th, 1908. Transfer books will be closed from September 15th to 19th, 1908, inclusive.

J. A. Jacobs. Sec.-Treas.

LA ROSE CONSOLIDATED MINES COMPANY.

Notice is given that a dividend of 3 per cent. for the quarter ending August 31, 1908, has been declared upon the outstanding capital stock of the company, and will be paid on the 20th day of October, 1908, to shareholders of record on October 2, 1908.

By order of the Directors, the transfer books will be closed between the 2nd and 20th days of October, 1908, both days inclusive.

Dated the 22nd day of September, 1908.

La Rose Consolidated Mines Company, per D. A. Dunlap, Secretary-Treasurer.

MARKET REPORTS.

Coke.

Sept. 25—Connellsville coke, f.o.b. ovens—

Furnace coke, prompt, $1.50 to $1.60.
Foundry coke, prompt, $1.90 to $2.00.

Metals.

Sept. 25.—Tin, Straits, 29.50 cents.
Copper, prime Lake, 13.50 to 13.625 cents.
Lake arsenical brands, 13.50 to 13.625 cents.
Electrolytic copper, 13.40 to 13.50 cents.
Sheet copper, 18 cents.
Copper wire, 15.25 cents.
Lead, 3.40 cents.
Spelter, 4.75 cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.25 cents.
Aluminium, 32 cents.
Nickel, 45 to 47 cents.
Platinum, $23.50 per oz.
Bismuth, $1.75 per lb.
Quicksilver, $43 per 75 lb. flask.

Silver Prices.

September 25	51 5-8	23 13-16

The production of coke from Connellsville and Lower Connellsville regions, in tons of 2,000 lbs., up to September 5, 1908, was 6,124,278 tons. The largest number of ovens in commission was 18,248 on August 29th. A minimum of 12,610 ovens was recorded for the week ending January 4th. Comparing these figures with the returns for 1907, we find that the output of coke up to September 5th of that year was 13,802,526 tons; the maximum number of ovens, 33,136 in August and September, and the minimum, 31,242 ovens, for the week ending March 28th.

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary. and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

CLYDE PATENT WIRE ROPE WORKS

Rutherglen, Glasgow, Scotland

WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. SPECIALLY FLEXIBLE ROPES for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. SPECIAL ROPE FOR LOGGING.

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of our haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz:

Nova Scotia: Wm. Stairs, Son & Morrow, Limited. **New Brunswick: W. H. Thorne & Co., Limited.**
Montreal and Toronto: Drummond, McCall & Co. **Vancouver, B.C.: John Burns.** **Winnipeg: David Philip, Portage Ave.**

HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.

Cables: "Ropery, Rutherglen." Codes: A. B. C. (4th and 5th Editions), A.I., Liebers and Private.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

NOW READY

Contains all the latest information up to within a few days of publication. The Standard Reference Work on Mines. 1,600 pages. In demy 8vo, cloth. Price 21/-, post free.

The book can be seen and obtained at the Offices of this paper.
Twenty-Second Year. Established in 1887.

The Mining Manual
For 1908
By WALTER R. SKINNER

22nd YEAR

A Record of Information concerning Mining Companies (Gold, Diamond, Silver, Copper, Tin, Iron, and other Mines, Collieries, Land, and Exploration Concerns, etc.)

Arranged in Three Sections, **Australasian, African, Miscellaneous,** with Tables of Crushings at ends of Sections, followed by List of Mining **Directors and Secretaries,** their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected; also **Mining and Consulting Engineers and Mine Managers,** with their Company connections, and a **Dictionary of Mining Terms.**

THE MINING MANUAL FOR 1908 contains particulars of no less than 3,150 COMPANIES, arranged in three sections, 450 Companies being: AUSTRALASIAN; 1,050 AFRICAN; and 1,500 MISCELLANEOUS (including Siberian, Mexican, Indian, Canadian, American, etc., and the Coal, Iron, and other mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; position at mine and ore reserves; detailed capital; calls; dividends paid; and the financial position as disclosed by the accounts.

The Lists of Directors (over 7,000) and Secretaries (1,750) include their addresses and descriptions and names of the Companies with which each particular Director or Secretary is connected.

A complete Alphabetical Index, including many useful items of reference, occupies 40 pages.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver, $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals, or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

Main Office and Works, Columbus, Ohio, U. S. A.

SULLIVAN CLASS "S" DRILLS

remove cores up ts 500 feet, and are so light and compact that they may be operated in any part of a mine—yet built so strongly and of such fine materials that they give as accurate results as the largest diamond drills made. The "S" is suitable for surface as well as underground work. It may be driven by air, steam, belt, or electric motor.

SULLIVAN DIAMOND DRILLS are more widely used for testing mines and mineral lands than any other prospecting drills made, because they remove a solid core from all rock formations penetrated, from soft coal or rock salt to the hardest ores. They will bore holes at any angle and to any depth, and will remove cores of any desired diameter.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLER

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

A FORWARD MOVE.

In making provision for courses in mining and metallurgy the University of Toronto, although largest of all Canadian universities in point of numbers, has lagged sadly behind her sister institutions, Queen's and McGill.

The School of Mining of Queen's University and the department of mining at McGill have world-wide reputations. Graduates of either institution have much of which to be proud. At Kingston and Montreal strong staffs of professors and assistants take care of some hundreds of students in mining and allied branches of study. At both places there are ample mining and metallurgical laboratories.

With the University of Toronto the case is different. While nominally there are courses in mining and metallurgy, in actuality the two subjects, geology and mineralogy, which should be entirely subordinate branches, have grown at the expense of the other essentials.

This condition has arisen, no doubt, because of the facts that geology and mineralogy have long been included in the general University curriculum, and not until within comparatively late years has mining been dealt with at all.

But, whatever the cause of this undesirable reversal of usual relations, the effects are evident. Queen's and McGill have more mining students than they can take care of. The University of Toronto is not in the race.

But the fact that the University of Toronto has neglected mining in the past does not prevent her from making a good beginning now. The recent appointment of Mr. H. E. T. Haultain to the chair of mining and metallurgy is a most hopeful symptom. Mr. Haultain is vigorous, competent, and enthusiastic. In the course of his professional career he has worked in many parts of the globe, including Canada and the United States. He has, moreover, the good fortune to be a Canadian.

We take it that the selection of Mr. Haultain to fill this most important chair is merely the first step towards a complete recognition of mining and metallurgy, as the foremost subjects in the curriculum of the School of Practical Science.

In its progress towards the goal of efficiency and practical usefulness, the School of Practical Science may count upon the support of Canadian mining men, and no better means could be desired to secure and retain that support than the appointment of such men as Mr. Haultain.

SPECULATION AND MINING.

Our excellent contemporary, the Mining and Scientific Press, has contracted a habit that is not in keeping with its normal tone of healthy, discriminating, and

alert intelligence. On more than one occasion it has emphasized its belief that mining is essentially speculative. To this belief we taken strong exception. Most of the catastrophes that have marked the history of mining in this and other countries would never have occurred had reasonable precautions been taken to remove the speculative elements in mining investment. It is true that mining promotions, as permitted by the lax administration of laws, or by the absence of a healthy public sentiment, are highly speculative. But it is wholly wrong to characterize the industry of mining as inherently speculative. The properly conducted mining enterprise carries no greater risks than does the ordinary commercial concern. Risks there are, and always will be, in all branches of human activity. Mining risks, sanely controlled, need be no greater than those taken by merchants or manufacturers. But it is illogical to damn mining merely because mining risks are described in different terms and because mining ventures are too often launched by predatory brokers. "Speculative" is a vague word. The Mining and Scientific Press is published in San Francisco. San Francisco was recently destroyed by earthquake. Another earthquake may raze the whole city to-day or to-morrow, or—not until doomsday. This adds an instructively speculative feature to the construction of buildings in San Francisco.

The green-grocer purchases perishable garden truck. He is a loser if he cannot dispose of his purchases within a given time. Millions of dollars are made and lost in gambling in wheat. Yet farming is not described as a speculative calling.

But it is unnecessary to multiply instances. Speculation may be defined as accepting heavy risks in the hope of making great profits. Every industry furnishes opportunity for speculation. No industry is free from the effects of human errors. Strikes and "Acts of God" cannot be foreseen. But it is the business of trained men to estimate possibilities, guard against error, meet competition, and provide for contingencies. In no industry are the rewards of industry, perseverance, and skill so rich as in mining. In no industry is there such utter need to root out the parasitic speculator.

Safeguards are provided for the mining investor. For a relatively small outlay he can ascertain the probable value of a prospect or the minimum value of a mine. He need not look far for honest and competent advisors.

In a word, it is idle and harmful to predicate for mining any higher degree of speculative uncertainty than is manifest in all the ordinary vocations of mankind. Mining should be a "business" in the strictest sense of that word.

A NEW FLOTATION PROCESS.

In our exchange column will be found an extract from a contemporary describing a new concentrating machine, which in simplicity of design is almost revolutionary. The machine is the invention of a Glasgow metallurgist. It consists essentially of a revolving iron tube, the inner side of which is grooved like a bolt-nut. A thin stream of water carries finely-crushed ore through this tube. Here each particle is repeatedly subjected to the surface tension of the water, as the grooved tube revolves. The impermeable sulphides are rapidly surrounded by a supporting envelope of air, and the permeable silicates and other gangue material are penetrated by the water. Thus when the ore enters the discharge apron the sulphides and gangue are completely separated. In practice three or four successive tubes are found necessary.

Unlike other flotation processes, the one in question depends entirely upon the surface tension of water. Neither oil nor chemicals are used.

From results reported it would seem that the new process is to have a large application, especially on the concentration of complex sulphide ores.

COBALT AND THE GLOBE.

Some weeks ago the Toronto Globe published a scathing arraignment of the morals of Cobalt town. Cobalt was condemned utterly by the Globe's sanguinary editor.

Cobalt, as a striving and self-respecting town, resented the Globe's utterances. A Cobalt newspaper demanded an apology from the Globe. No apology was forthcoming.

In this instance the Globe, unable to shift the responsibility of its indiscretion, and unwilling to make proper amends to the citizens of Cobalt, bethought itself of the expedient of using a Saturday supplement in which Cobalt should figure largely. This was done.

Cobalt itself may be left to decide whether this does or does not remove the *casus belli*.

NEW BRUNSWICK OIL SHALES.

The Dominion Government early this summer sent Dr. R. W. Ells, of the Geological Survey, to Scotland with instructions to look into the Scotch oil-shale industry. From the property of the Albertite Oilite and Cannel Coal Co., Limited, a parcel of 42 tons of New Brunswick oil-shale was shipped to Pumpherston, Scotland, for experimental purposes.

Dr. Ells' report is to appear shortly. Meanwhile, from unofficial sources, we are informed that the test was most satisfactory. The Scotch shales, which are the basis of an exceedingly prosperous industry, yield an average per ton of 28 gallons of crude oil and 75 pounds of ammonium sulphate. As compared with these figures the New Brunswick shipment showed a yield per ton of 40 gallons of oil and 75 pounds of ammonium sulphate. This indicates that this comparatively large shipment was richer than the richest Scotch shales.

The property of the company that controls the New Brunswick oil-shale deposits covers 190 square miles in the counties of Westmoreland, Albert and Kings. Seven veins, ranging in thickness from 4 feet to 8 feet, have been opened. They lie between well-defined walls. The

veins show a dip of about 25 degrees N. Their strike is roughly east and west. There is every promise of an enormous supply.

When it is remembered that the Scotch oil-shale companies pay dividends at as high rates as 50 per cent., and, further, that the New Brunswick deposits are probably more workable in every respect than the Scotch, it becomes a matter of wonder that these rich deposits have remained so long unworked.

In a later issue the Canadian Mining Journal will publish a complete account of these Canadian oil-shales.

CORPORATIONS AND POLITICS.

The Nova Scotia Steel and Coal Co. and the Dominion Coal Company have issued a notice to their employees instructing them to refrain from active participation in the canvass at the approaching Federal elections. All officials of the companies are prohibited from using their official positions to influence unduly any voter. The notices state that it is expected and desired that every employee will use his vote according to his convictions.

It is well that large corporations should clear their skirts of complicity in politics. We use the word "complicity" advisedly, for it seems a fitting term as politics are conducted to-day. It is extremely undesirable that corporation officials and their policies should be dragged into the political game. Whenever this has happened the results have been anything but happy.

There are officials, and there always will be officials, who are unable to understand that any power or influence attached to their position, is the power of the corporation, and none of their own. A corporation official is the servant of his employers in his official capacity. In that capacity he may be temporal lord of thousands, but as a citizen he is the possessor of one vote, and nothing more. If he cannot divorce his official power from his position as an elector, he loses, or should lose, his usefulness to the corporation he is supposed to serve.

We think the straightforward pronouncement of the two Cape Breton corporations referred to is in every way commendable.

DOMINION COPPER.

The Dominion Copper Company, successor to the Montreal and Boston Consolidated, has applied for a receivership. Dominion Copper inherited a legacy of trouble from its predecessor. From October, 1907, until July of this year, its mines were closed. This summer, for a period of seven weeks, the plant and mines were active. Failure to make a payment of sixty thousand dollars, due on its sinking fund under terms of a mortgage held by the National Trust Company, is the immediate cause of the receivership.

The Dominion Copper Company is capitalized at $5,000,000, in shares of $5. It has also a bond issue of $1,000,000, only a small amount of which has been retired.

The Dominion owns and operates five mines near Phoenix and Greenwood. It also owns some high-grade gold-silver claims. Its smelter at Boundary Falls has a daily capacity of 800 tons of copper ore.

Its largest mines, the Rawhide and the Brooklyn, are in good condition, and show heavy reserves of fair copper ore. Within the last two years large sums have been expended in plant and mine improvement. At present, therefore, the physical condition of the company's properties is apparently excellent.

Re-organization is to follow. There is every reason to believe that the Dominion Copper Company will soon resume production.

YUKON'S GOLD.

Cheering news comes from the north. Changes and improvements in the methods of hydraulicking have made possible the handling of gravels in greater quantity than heretofore. The enlarged scale upon which dredging is performed makes profitable much gold-bearing material neglected in the past. The season of work has been lengthened, power cheapened, gold recovened, gold recovery gradually improved, until the effects are tangibly expressed in a largely augmented annual gold output.

For 1907 the reported production of gold in the Yukon was $3,150,000. The figures for 1908 will probably exceed $5,000,000.

MOISTURE IN COKE.

The moisture contained in coke is a serious item in metallurgical works. When immersed in water, coke absorbs as much as 35 per cent. of its weight. So pronounced is this hygroscopic power that coke containing 4 to 7 per cent. moisture after quenching often is found to carry 10 to 12 per cent. when received by the purchaser. The absorption depends of course upon the humidity of the atmosphere. But the facts ad luced accentuate the need of great care in quenching.

The production of quicksilver in the United States has been falling off steadily during the past five years. Where there were 20 producing mines in 1904 there are now but ten. During this period the production has decreased from 32,000 flasks of 75 lb., to about 17,000.

The singular phenomenon of hard steel being cut by a rapidly revolving disc of soft steel has been somewhat puzzling. A microscopic examination by an English engineer, F. W. Harbord, has now shown that the metal acted upon is heated nearly or quite to the melting-point of steel, but only at the point of contact with the disc.

The Development of the Lash Process for Making Soft Steel in the Electric Furnace.

In our February 1st, 1908, issue we published a description of the Lash Process for making steel, and outlined in a general way what The Canadian Lash Steel Process Co., Ltd., was undertaking in the way of the development of this process in the electric furnace, and promised our readers a report of the results after

FIG. 1—BUILDINGS—CANADIAN L. S. P. CO.

the plant was in operation. This company having built their plant, and completed their test runs, we give below a description of the same, and the results of these runs. A brief description of the process is as follows:—

The Lash Process consists of making a mixture of concentrated magnetic ores, or iron ore sands, granulated pig iron and carbon, and charging the same into either an electric or open hearth furnace and producing steel. It is not a direct process in the strict sense of the word, but is an ore and pig process, the ore, however, being greatly in excess of the amount of pig iron used, and practically eliminating the scrap, using only such scrap as is made in the regular operation of a steel works.

The amount of pig iron required to make a ton of steel is less than one-half of what is required in regular open hearth practice when the mixture is used in an electric furnace, on account of its non-oxidizing atmosphere; this feature, coupled with the fact that the rest of the mixture is iron ore, which is, of course, the cheapest source of metallic iron, helps to produce a ton of steel ingots at a price much lower than they are produced in regular practice, either in the United States or Canada, figuring the electric power required at its regular market price as sold in large quantities.

Figure No. 1 gives a view of the plant, which is located in Niagara Falls, N.Y., corner 28th Street and Buffalo Avenue.

Figure No. 2 gives a view of the furnace just before starting the plant, which furnace is of the Heroult type of 1,000 horsepower capacity, and is capable of making 4 to 5 tons of steel in one heat.

Figure No. 3 shows the same furnace in operation, and was taken during the making of the twentieth heat.

Figure No. 4 shows the hydraulic tilting mechanism of the furnace, and the back of the furnace in a tilted position while pouring.

Figure No. 5 shows the transformers, which were made by the General Electric Company, and are of 750 k.w. capacity.

Figure No. 6 shows the casting crane with the slag ladle hanging thereon, and a view into the pit, where the casting was done. (All ingots cast at this plant were bottom poured in groups, and were 6x6 inches square, weighing on an average 500 pounds each.)

Figure No. 7 shows the mixing plant, in which the material was mixed that was charged into the furnace, the ore, granulated pig iron or cast iron borings, and carbon in the form of coke, charcoal or anthracite caol, being put into this plant and thoroughly mixed with a small proportion of slacked lime, the slacked lime being used to keep the material in bond.

The operation of this plant was as follows: A mixture of 67 per cent. of magnetic iron ore, 23 per cent. of cast iron borings or granulated pig iron, 10 per cent. of coke dust was put into the mixing pan in batches of about 500 pounds and allowed to thoroughly mix for 10 or 15 minutes, when about 4 per cent. of the slacked lime was added. After this material was thoroughly mixed and a sufficient quantity had been accumulated, a sufficient amount of the same to make 4 tons of steel was charged into the electric furnace; about 100 pounds of steel scrap was scattered over the top of the same, and a small bar was put into the furnace to form an arc for the electrodes; the electrodes were then lowered into

FIG. 2—ELECTRIC FURNACE 1,000 H.P. CAPACITY.

position, the current turned on, the furnace closed up tight, and the entire batch of material was melted. After the same was thoroughly melted, the slag was poured off into the slag ladle, and a refining slag put into the furnace for the final refining of the metal; on completion of this operation, the metal was poured into

the casting ladle, thoroughly draining the furnace, and then cast into ingots, when the next charge was added and the operation repeated as described above.

A full report describing the entire operation at this plant of all the heats made would be very lengthy.

Fig. 3—Furnace in Operation.

During the making of the first ten or twelve heats no attention was paid to getting definite results, but the first runs were for the purpose of familiarizing the men with the process and the furnace operation, and also to ascertain the best methods of charging, refining, etc.

Some of these heats were made with the material in the form of bricks, which were being preheated in the stack of the furnace before charging, and while this method did not give the best results in every respect, it is believed that the future operation of a large plant would be along these lines, or along the lines of preheating the mixture without briquetting, because from a theoretical standpoint, this method is ideal, making use, as it does, of the waste heat of the furnace for a partial reduction of the material.

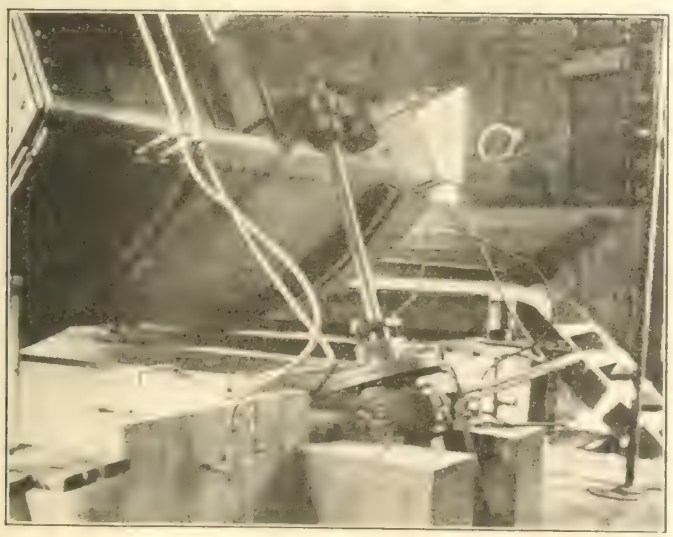

Fig. 4—Furnace Tipping Arrangement.

The best results obtained came from the method of charging loose material into the furnace in bulk; these results proved beyond a doubt the commercial possibility of the process for making steel from a mixture in which a large quantity of ore is used, and it leaves the possibility for still better records, when proper arrangements are made for a preliminary treatment of this mixture by the waste heat of the furnace before charging.

An average of the second half of the run in which the material was charged in bulk, as above described, gave a result that proves conclusively that one gross ton of steel can be easily made for one-quarter of an electric horsepower year.

An average of the same heat proved that the electrode consumption would be less than 50 pounds of electrodes per gross ton, and the yield of the metallic contents charged into the furnace, owing to its non-oxidizing atmosphere, is better than that obtained in the regular open hearth practice.

In making steel by this process, and laying aside entirely the fact that it is a commercial proposition, owing to the low cost of production, the results obtained in the quality of steel made were more than satisfactory. It must be borne in mind that the largest part of the material from which this steel is made is iron in its native state, in the form of ore, and that when this material is mixed with granulated pig iron all of the metallic contents come direct from the native

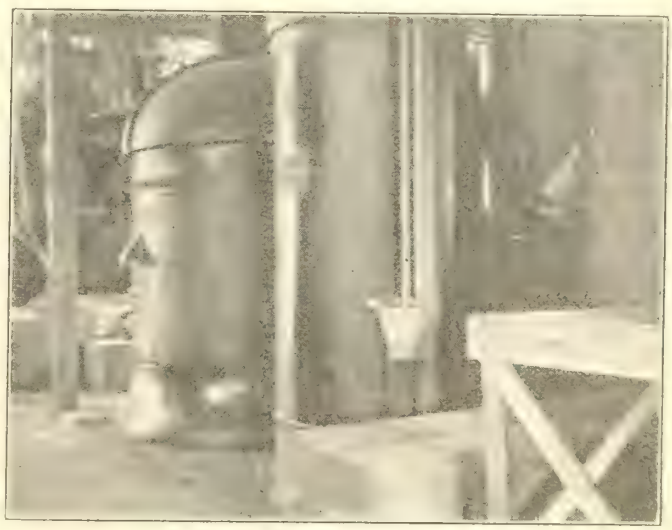

Fig. 5—Transformer Room.

iron. The physical qualities of the steel thus made are in every respect superior to steel made by the regular process of scrap and pig, even when the chemical analyses are about the same.

Then the high heat in the electric furnace permits of a better condition for refining and pouring. In a number of heats made at this plant, in which the sulphur and phosphorus in the mixture were above 0.2, these in the steel were almost eliminated, a result that it would be impossible to bring about in the regular open hearth practice.

Mr. Horace W. Lash, the president of The Canadian Lash Steel Process Co., Ltd., is a steelmaker of national reputation, and for years has been closely associated with the steelmaking world; he is vice-president of the Garrett-Cromwell Engineering Co., of Cleveland, Ohio, Mr. Lash has spent four years perfecting this process in an experimental way before these tests were made, and the results of the tests have proven beyond a doubt that the Lash process is in every respect a commercial proposition. Particularly is this so for Canada, which country is greatly blessed with numerous water powers, and an abundance of magnetic iron ore, which

is just what this process requires for its development.

The tests at this plant were under the supervision of Messrs. FitzGerald & Bennie, of Niagara Falls, N.Y., and Mr. Robert Turnbull, of St. Catharines, Ont. Messrs. FitzGerald & Bennie and Mr. Turnbull stand high in their profession of metallurgical and electrical experts, and the greatest care was exercised on their part to obtain accurate results.

We quote the following from Messrs. FitzGerald & Bennie's report:—

"In a general consideration of the electric furnace experiments there is reason to be satisfied. So far as the power consumption is concerned, the results obtained show that no difficulty in reaching a power consumption of one-quarter horsepower year per ton of steel produced need be expected. The only serious problem which we have been faced with in the experiments is that of electrode consumption. However, if the conditions of the experiments are considered, there

Fig. 6—Casting Crane

is reason to believe that this difficulty may be met successfully. There is one other point to be noted in this connection. The Lash process so far has been tried only in the Heroult furnace, where carbon electrodes are used, and this difficulty would not have to be faced in the induction furnace of the Rochling-Rodenhauser design."

Over $30,000 was spent by The Canadian Lash Steel Process Co., Ltd., in building this plant, and conducting these tests, and the results have brought forth conclusively the following:—

First—That cheaper steel can be made by this process than by the regular open hearth practice owing to the reduction in the amount of pig iron required, and the fact that the rest of the metallic content is in the form of ore, which is iron in its cheapest state. To anyone familiar with the steel trade, this cost can be easily figured when the cost of ore, pig iron, carbon in any form, and water power is known. On $3 ore, $18 pig iron, and $15 power, ingots can be made for less than the cost of the pig iron.

Second—The quality of the steel is very much better, owing to the material in the charge coming direct from its native condition.

Fig. 7—Mixing Plant

Third—The control of the heats and temperatures is absolute, and the trouble due to impurities in fuel is eliminated.

Fourth—The carbon content of the bath can be brought under absolute control, as it is only necessary to slightly vary the mixture to bring out any carbon content desired.

Fifth—The cost of building a plant of a given capacity is much less than a plant for regular open hearth practice on account of the elimination of all producers, checker work, underground flues, etc., the electric furnace being nothing more than a large-sized lined ladle.

Sixth—The attendance required should be less, as the material is simply charged into the furnace, the

The S. Bell Yard

furnace is closed up tight, and the power applied. Owing to the character of the material that is charged, and the electrical control of the operation, no attendance is required until the melt is made. It therefore becomes a mechanical proposition throughout, in which the materials are all handled by machinery, and the furnace is self-regulating. It is possible to charge a

large size furnace in less than two minutes. These facts, when compared with the pig and scrap proposition, which takes considerable labor to handle, are apparent to those familiar with the steel business.

Seventh—The cost of refractories, repairs, etc., will be very much less, and there should be no interruption to continuous operation of a plant, because a complete furnace fully lined, ready to go into operation, can be kept as a spare, and with the proper crane arrangements can be set in the place of the furnace needing repairs, which furnace can be taken to another building for this purpose. Therefore, it is apparent that the cost, and care of checker work, producers, flues, etc., are entirely eliminated. Owing to the construction of the electric furnace the roof is very much stronger and better maintained.

Finally—The control of the heat for the elimination of impurities, and the handling of the steel, and the fact that the amount of impurities charged into the furnace is always known, gives a condition for the making of high-grade material that cannot be obtained by any other known process.

BATTERY AND CYANIDE GOLD SMELTING.

By A. Thomas (Member).

(Paper read before the C. M. and M. Society of South Africa.)

As it is some time since the subject of gold smelting has been discussed by this Society, the following notes are written with the object of giving a brief outline of some present practices, and of providing an opportunity during discussion, for members to bring forward other methods at present in vogue.

The separation of the mercury from the gold is done in cylindrical retorts, made of cast steel, measuring 53 in. long, 12 in. in diameter, and 1½ in. thick. The retorts rest on two water cooled bearers, with the usual water jacketed condenser for the mercury fumes. The flue of a retort furnace has three openings, measuring 11 in. x 8 in, arranged above the retort one over each end, and the other over the centre, thereby insuring a uniform temperature over the whole body of the retorts. This arrangement of the flue is necessary, as with the single flue retort furnace one part of the retort is generally heated too strongly, whilst other parts are insufficiently heated to volatilize the mercury completely. The capacity of this retort is 5,000 oz. of amalgam, and in charging, semi-circular trays are used. These are white-washed inside before receiving the amalgam, and care is taken not to fill the trays too full. The doors of the retort are sealed with a joint made of asbestos cord soaked in water. As soon as the mercury begins to come through the condenser the fire is checked and a uniform temperature maintained for about two hours, or until the mercury ceases to come off. The temperature is then raised to expel the remainder of the mercury.

If the temperature is too high in the early stages of retorting, the distillation will be too violent, and sputtering of amalgam in the retort is likely to ensue. The time required for retorting is from 4 to 4½ hours.

After removal from the trays, the gold is weighed into 1,000 oz. lots and smelted in No. 40 plumbago crucibles; a little borax is added as the gold melts down, but this is removed by skimming, after being thickened by the addition of a little fine sand. The bullion is afterwards cast into bars, which show a loss in weight of about .72 per cent. on the retorted gold. The mercury is afterwards weighed and returned to the mill. The difference between the weight of the amalgam charged into the retort and the weight of gold and mercury recovered is about .14 per cent. on weight of amalgam. Several assays of the retorted mercury have been made, and in each case only a trace of gold found. The coal consumption for retorting 5,000 oz. of amalgam is about 350 lb.

The fire boxes used for calcining the zinc gold slimes are rectangular in shape, measuring 44 in. x 22 in. A tray made of 2 in. cast-iron with three sides turned up 1½ in. is placed over the fire box. The trays in which the slimes are calcined are placed over these furnaces and are made of ⅛ in. mild steel, 48 in. long, 26 in. wide and 8 in. deep. Before receiving the slimes these trays are white-washed, as this prolongs their life and prevents the slimes from adhering to the bottoms, especially if the temperature has been too high during the calcination process. Great care must be taken in carrying out the calcination, as upon this the success of the smelting operation depends. The temperature is kept low at first and gradually raised as the operation proceeds. As a rule, about three hours is required for a successful calcination. The usual loss on this operation is about 42.4 per cent. of the original weight. Tests seem, however, to show that the bulk of the loss is due to moisture, which may run up to as much as 38 per cent., the remaining 4 per cent. may be due to the removal of carbonaceous matter, and other changes, which may cause a loss of weight. A curious feature of the calcined slimes is the presence of a purple color, which would seem, though I am not positive on the point, to vary in intensity in proportion to the richness of the slimes. Acording to Muller (see Metallurgy of Gold, by T. K. Rose, p. 35), gold in a very finely divided state gives a purple color i nthe presence of alkalies and alkaline earths, and it may be that this purple color is the same as mentioned by Muller. On completion of the calcination the tray is removed from the furnace, and when cool, taken to an enclosed room, where the calcined slimes are weighed and fluxed. Every precaution should be taken at this stage to avoid unnecessary handling and consequent dusting of the slimes.

The fluxing is carried out as follows:—The calcined slimes, which are more or less caked, are weighed direct from the trays without any grinding whatever. Plumbago crucibles No. 100 with clay liners are used for smelting. The slimes are weighed and placed in the pots with the required amount of manganese dioxide The pots are only filled to within 4 1-2 to 5 inches from the top, the rest of the space being used for the other fluxes, composed of borax and silica, old crushed liners being used as a source of silica. The following may be taken as a representative charge: Calcined slimes, 100 parts; manganese dioxide, 7.5 to 10 parts; crushed liners, 25 parts; fused borax, 20 to 25 parts.

Naturally, the flux is used within certain limits, according to the quality and physical features of the slimes after calcination. All new plumbago crucibles are subjected to a preliminary treatment before use, thus increasing their life to a considerable extent. The treatment is as follows:—They are placed in the furnace and heated for 30 minutes, to remove the glaze, after cooling they are placed for 45 minutes in a saturated solution of borax, and are afterwards dusted over with powdered borax and placed over the calcining furnace to dry, and when dry, reheated in the reverberatory furnace until the borax fuses. New clay liners, whenever possible, are used in the first charge of the smelt. This obviates the necessity of suddenly subjecting them to the high temperature of the furnace prevailing with subsequent charges.

A type of furnace which, with a few slight alterations, would be quite suitable for this work, is the old reverberatory pan furnace, known locally as the Tavener furnace; one point I may mention in connection with furnaces used for smelting rich gold bearing materials, is the lack of proper condensing chambers in the flues. I am convinced that some kind of condensing chamber is necessary and should be attached to all furnaces smelting finely divided and rich product, such as cyanide gold slimes. Even with all the precautions that can be taken in fluxing, such as using a borax cover, or placing covers on the pots, I have every reason to believe that gold is carried off to the flue, both mechanically and by volatilization.

The buttons of gold obtained from the fusion are usually of high grade, and ready for casting into bars. Occasionally, a thin skin of matte may appear on a few of the buttons, and when this occurs they are arranged so that those with the matte are placed in the same crucible as the highest grade button of the smelt, thus averaging up the fineness in the bars. No attempt is made to desulphurize the matte in smelting, but this is skimmed off and kept for future treatment with the bye-products in the pan furnace, where it will be desulphurized with battery screens. This matte generally occurs in case of cracked liners when the slag comes in contact with the graphite crucibles. My experience goes to show that to a very large extent the fineness of the bullion produced on these fields depends mainly on good calcination. Perfect calcination has two other great advantages, firstly, by reducing the bulk of the material; secondly, by perfect oxidation of the base metals, doing away with the necessity of using a large quantity of oxidizer in fluxing, thus reducing the value driven into the slag—particularly of the silver.

For very base bullion, owing to the presence of metallic lead and copper, I find that cupellation with clean lead is the only satisfactory method of bringing up the grade. This, however, should not be necessary on these fields, as low grade bullion is rare and unnecessary.

In casting cyanide bars it is usual to keep their weight in the neighborhood of 700 oz. A point that has often been raised on these fields, is to what degree of fineness should bullion be brought. At present we have all kinds of pains and penalties to avoid at the hands of the refiners in London. This seems rather extraordinary when we consider the tonnage, for that is what it amounts to, of the gold we turn out. A mine that refines its gold up to over 900 parts per 1,000 fine receives no better terms than one which just reaches the mark of 900 gold and silver. There is no doubt that every penny we spend on refining our bullion beyond the point necessary to escape the penalties, is to my mind, unnecessary. The present system is certainly not satisfactory, and would bear thorough investigation at the hands of those who have the disposing of the gold on behalf of the mines.

Another point also suggests itself, why should we ship all our bullion home for refining? I can see no reason why a refinery should not be established on these fields. The technical part of the work can be successfully carried out here, but I will leave the discussion of the financial side of this question to members who may have more data at their disposal.

For the treatment of bye-product many mines are equipped with the usual kind of reverberatory pan furnace. As the construction of the furnace is the main factor which governs efficiency and working costs. I give the following dimensions of a furnace of this kind, hoping they may be of use to some of the members.

The pan in which the furnace hearth is built is made of ½ in. iron, measuring 9 ft. x 6 ft. with a depth of 24 in.:—

Size of grate in fire box, 3 ft. 6 in. x 3 ft.; from fire box of grate to top of roof, 2 ft. 4 in.; top of bridge wall to roof, 11½ in.; size of furnace hearth, 7 ft. 6 in. x 3 ft. 6 in:; bridge end of hearth to roof, 2 ft. 5¾ in.; centre of hearth to roof, 2 ft. 6 in.; lowest point of roof to hearth, 1 ft. 7 in.; the hearth of the furnace has a fall from all points to tap hole of 3½ in. to 1½ in.; uptake flue from furnace, 2 ft 6 in. x 9 in.; capacity of furnace for lead bullion 4,200 lb.=61,268 oz. troy.

The bye-products consist of the slag from the smelting of gold zinc slimes in the reverberatory pan furnace, ground up crucibles, liners, etc. In treating these bye-products, the aim is to produce a liquid slag of low specific gravity, and thus reduce as much lead as possible from the materials treated. This is done by the addition of metallic iron in the form of battery screens. As a precaution against any residual high values of the precious metal in slag, the charge, prior to withdrawing the slag, is given a wash down with litharge and coal dust.

All variations in the charges smelted are regulated by experience. It would be very interesting to know by analysis the exact composition of the slag and other materials to be treated and so be able to flux from a theoretical standpoint. However, as these parcels of slag and other bye-products are not very large, and the composition of them varies from time to time, an analysis would not furnish any definite information for the treatment of future bye-products.

The present method is crude, but the value of the residual slags shows that the results are satisfactory. Naturally, this method is only applicable in a case similar to the one we are dealing with, because fully 90 per cent. of the material treated has already been fluxed, and merely requires re-smelting and reduction of the metals. The principal material to be smelted being the slag from the zinc slimes smelt, this is always taken as a base from which to work. When there is a large quantity of refractory materials to be smelted, it is worked off in small lots. Should these present any difficulty, the amount of assay slag usually added to the charge is slightly increased, ground up liners, or any other gold bearing silicious material is added in small lots to each charge, as the slag from the cyanide smelt is nearly always basic, and some protection is need for the furnace lining.

In commencing a smelt, a few bars of lead are

placed in the furnace, so as to form a bath, and prevent the slag from corroding the bottom of the furnace. The first charge is made up and its behavior in the furnace carefully noted, so that any defects may be remedied in the succeeding charges. It is sometimes found necessary to return the slag to the furnace for re-treatment on account of the high values contained therein. The following is a brief account of a bye-product smelt.

Amongst the materials treated were, reverberatory pan furnace slag, bullion furnace ashes, extractor house sweepings, old cupels, brick from furnace bottoms, calcining trays, battery screens, elephant cord from battery, assay slag, etc.

The mixture was made up into 14 charges of about 900 lb. each, and contained 9 per cent. lithage and 5.5 per cent. iron, in the form of battery screen and old calcining trays.

The average value of the slag drawn off, assayed as follows:—

Gold, 3.99 dwt. per ton; silver, 337.59 dwt. per ton; lead, 6.5 per cent.

The weight of lead bullion recovered = 19,143 oz. troy. The total litharge added only accounts for 12,-711 oz,. thus showing a gain of 6,432 oz. After deducting 797 oz., the weight of the gold and silver recovered by cupellation, there remains a surplus of 5,635 oz. of lead, which has been recovered from the material treated.

In this smelt the last few pots of slag drawn off are put aside for treatment in the next smelt, since fine shots of lead may be skimmed off. Before tapping the lead bullion off, the metallic lead is concentrated and purified by oxidation and the dross afterwards taken off. In this particular smelt the dross carried 28 per cent. metallic copper, the remainder being oxide of lead and finer shots of metallic lead. The cupel used in this smelt was made of bone ash, manufactured on the mine. The bones were collected from the kitchen at the native compound, and burnt in the cupel furnace, an iron plate being inserted on the cupel so as to form a bottom for the furnace. The burning presented no difficulty, and the calcination was complete in four hours. It is most important that the bones should be completely burned, so as to expel all animal and carbonaceous matter. The loss in weight during calcination is about 54 per cent. The bone ash obtained was equally as good, if not better than than the imported article, at less than half the cost. In preparing the bone ash for making the test, I used 14 lb. caustic potash in solution to 400 lb. bone ash with satisfactory results.

In presenting these brief notes I do so with the hope that the members engaged in this class of work will raise a discussion which will serve to bring forward a few of the newer innovations in smelting on these fields, and so bring our published information up to date.

Coal Washing as Practised by the Nova Scotia Steel and Coal Company, at Sydney Mines, Cape Breton, N.S.

From Transactions of the Canadian Society of Civil Engineers.

By C. L. Cantley, Stud. Can. Soc., C.E.

The cleansing of coal to fit it for metallurgical purposes is a branch of the art and science of ore dressing which has become prominent only at a comparatively recent date in America. The reasons for this are quickly brought to mind when we remember the growing scarcity of pure fuel and the refinements of metallurgical methods which now make fuel treatment necessary, except where Nature has been especially kind to the metallurgist.

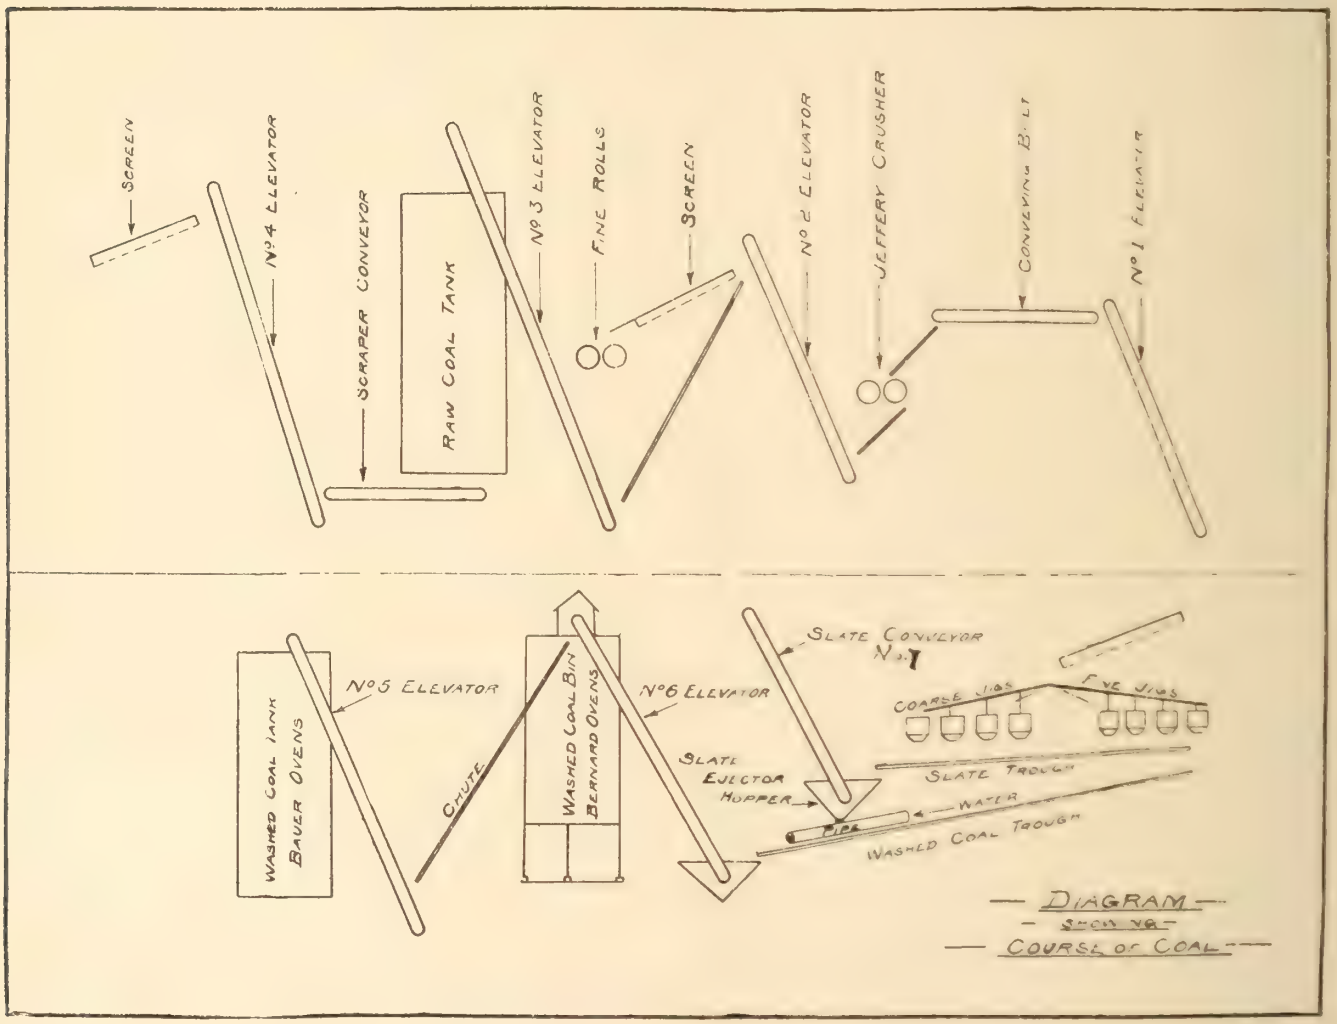
In Canada, the greater part of our fuel is not sufficiently pure for the economical smelting of iron, and hence it was that one of the first coal washers to be built and operated in America was laid down in 1892 at Ferrona, Nova Scotia, by the New Glasgow Iron, Coal & Railway Company, at that date a constituent of a company which afterwards became the title company.

The success obtained on the product of the neighboring mines induced Mr. Graham Fraser, at that time managing director of the Nova Scotia Steel & Forge Company, to carry out a series of experiments in and about the year 1894 on other Nova Scotia coals, and especially to test the coals of Eastern Cape Breton with a view of seeing whether a good enough coke could be made to warrant the establishment of an iron and steel industry on that island.

The experiments proved conclusively that by this method of treatment coals containing a high percentage of ash and sulphur could be so prepared as to make a coke of good quality, at atreatment cost not exceeding ten cents per ton, and it is largely to these successful tests we owe the establishment of the iron and steel industry of Cape Breton.

Thus we see, from the outset, the fundamental importance of this branch of ore dressing which has made possible one of the greatest industries in Eastern Canada; this is further emphasized by the recent troubles in Canadian steel-coal circles brought about by coal being supplied which, it was claimed, could not be sufficiently purified by washing to make good metallurgical coke.

The Nova Scotia Steel & Coal Company in 1896 purchased the entire property of the General Mining Association of London, which operated the well-known "Old Sydney" main seam in Sydney Mines, Cape Breton. The intention then was to utilize part of the coal mined for the manufacture of coke to be used in iron blast furnaces, and in 1899 the plant described in this paper was laid down at the colliery, the general scheme being similar to that of the plant previously erected at Ferrona. As originally designed, by Stein & Boericke, metallurgical engineers of Philadelphia, and erected, the plant was expected to handle 300 tons of coal per day of ten hours. It has, however, been much altered in details, chiefly of elevators and waste disposal, so as to have a uniform washing capacity throughout, and, as a consequence, the output is now over 500 tons per day.



The plant is situated in the immediate vicinity of the

colliery, from which it formerly drew all its coals. Now, however, the coals treated are screenings collected in cars from several collieries, and are what is locally known as culm or duff, that is to say, the screenings removed from the run of mine coal as prepared for the market. These screenings include practically all the fire-clay contained in the clay parting between the coal seam and the roof and the foot wall. The undercutting being in the clay-band next the foot wall, the proportion of ash in these screenings is from two to three times as great as in the seam coal proper.

An outline of the whole process is shown in the appended sketch.

The cars of screenings are emptied, as required, into No. 1 elevator pit, and the coal is lifted by bucket elevator to a Robins belt conveyor, which carries it 135 feet, over sidings, to the breaker house, where it is lowered by chute to a modified type of Jeffery rolls. These rolls are 24 inches in diameter, and turn at 180 and 270 revolutions, respectively, per minute in opposite directions. The original rolls (the frame being of cast iron) were designed with one roll stationary and the other adjustable, the adjustable roll being held within a half inch of the other by means of a counter weight acting through a toggle joint applied to each bearing of the moveable roll, it being necessary to have one adjustable on account of foreign material, such as bolts, spikes, etc., finding their way into them with the coal.

While the toggle joints gave very good results for small pieces of iron and rock, they would not allow the rolls to open up quickly enough to pass a two-inch machine pick, and this caused frequent breakages of the roll frame. To overcome this trouble the cast iron frame was discarded and the original rolls, bearings, and toggle joints were mounted in a frame consisting of two steel channel irons on each side, with a top and bottom cover plate, forming a box girder; to this girder is fastened, on each end, cast steel pedestals to receive the bearings, these last being held to the girder by means of four three quarter-inch machine bolts. The effect of this construction is that when a machine pick passes through the rolls, and the toggle joint does not act quickly enough, the four three-quarter-inch bolts, holding the pedestals to the girder frame, are sheared off, allowing the rolls to separate and causing no other damage than the loss of the four bolts, which are easily replaced, and the machine put in running order again.

The product is elevated by No. 2 elevator and deposited on a shaking screen with half-inch perforations. The screenings fall directly to No. 3 elevator pit; all portions larger than half-inch going over the screen into plain rolls, 16 inches in diameter, and running at 80 revolutions per minute, and thence to No. 3 elevator pit. From here all the coal of half-inch diameter and under is elevated by No. 3 elevator to the raw coal storage tank, which is built of steel, brick lined. This storage tank is self-trimming, and holds 1,000 tons, a fea-

ture which permits a supply of crushed coal to be kept one day ahead. Thus the washer proper is enabled to run on a day when the collieries are idle. The bottom of the tank is designed with two rows of parallel openings, fitted with sliding covers, each in line with a horizontal scraper conveyor delivering the crushed coal to the foot of No. 4 elevator, which delivers it in turn upon the shaking screen. This last has three-eighth-inch perforations, and being set at an angle of about 15 degrees, is supported upon rocker arms, and has an eccentric motion closely resembling that of hand screening. Owing, however, to the fine coal being more or less damp, it is impossible to separate the two sizes on a dry screen, so that, as the coal is delivered to the screen, it is met with a number of jets of water, which flush the coal through the screen plates. When the screen was flushed with the ordinary coal washing water the perforations in the jet pipes became plugged up, consequently clear water has to be used, and a cheap and convenient supply is found in the circulating water from a surface condenser, connected to the main centrifugal pump engine; this water being warm, is less trying for the jig tenders, who have their hands immersed continually. The combined effect then of the incline and the supply of water is to rapidly flush away by flume those screenings under three-eighth-inch to the fine jigs. The remainder, under half-inch and greater than three-eighth-inch, being sluiced to the coarse jigs.

There are four coarse jigs on one side of the building, and as many fine ones on the other, all of them being essentially modifications of the Luhrig jig, and designed especially for coal washing work by Mr. Stein, the engineer whose firm had charge of the erection of the plant. The fine jigs, styled "Standard two-compartment finecorn jig" by the designer, are built of wood, and wash 7½ tons of coal per hour.

Thus about 65 per cent. of the coal is washed by the fine jigs, since only three of the coarse jigs, with a capacity of six tons per hour each, are used at a time. The fine jigs, which have one compartment fitted with quarter-inch perforated plates, and the other with three-eighth-inch perforated plates, are run at 135 pulsations per minute. The feldspar used in the bed is of five-eighth-inch cubes. The coarse jigs are run at 72 pulsations per minute, and have a bed of seven-eighth-inch feldspar varying from 2 to 4 inches in thickness, depending on the amount of slate flowing. The purified product from the jigs is sluiced to the washed coal bin, while the slate runs to a waste bin, from which it is removed by No. 7 elevator to the slate bin in a storage tower, or flushed away by the slate ejector.

The water from both these bins, carrying in suspension certain fine coal and extremely fine particles of slate, returns to the sludge tank, directly under the jigs. There this fine material settles, and at proper intervals is drawn off. This tank, being the reservoir to which all leakages drain, also acts as a sump for the washer, and the centrifugal circulating pump drawing from it uses the water over and over again. Thus the only loss of water is that caried away by the products as moisture, a small amount as leakage, and that used for flushing purposes. This amounts, in all, to about 25 per cent. by weight of the coal washed.

The washed coal is all elevated to a drainage and storage tower by No. 6 elevator, which is equipped with perforated buckets, as also are the elevators Nos. 5 and 7, and the amount required for the coke ovens located nearby is lowered by chute and re-elevated by No. 5 elevator to another tower. This additional handling is found to pay, owing to the reduction of moisture by drainage.

The amount of water required in circulation is about 2,000 gallons per minute, and is supplied by a 12-inch centrifugal pump direct connected to a 12x10 vertical engine, running at 250 revolutions per minute. This engine exhausts into a surface condenser, the circulating water of the condenser being used as mentioned above to flush down the coal over the shaking screen.

As originally laid down, a 100 horsepower engine supplied all the power necessary, but now electricity is used for motive power as follows: Crushing house complete, including elevators; one Westinghouse 75-H.P., 60-cycle, 3-phase, 200-volt, 650 revolutions per minute, induction motor; washer house proper, jigs, etc.; 50-H.P. induction motor; Bernard tower; 30-H.P. 220-volt induction motor. All the motors are of the same type.

The following analyses are in each case averages of many determinations, and represent as close an approximation to the actual composition of the products as can possibly be obtained. The raw coals from the three separate colleries have been analysed at regular intervals over a period of several consecutive months, and give the following results:—

Coll.	Moist.	Vol. and Comb. Mat.	Fix. Carb.	Ash.	Sulphur.
A	4.86	29.11	56.73	14.87	2.14
B	5.96	28.38	57.38	14.23	2.09
C	6.51	23.11	54.27	22.61	2.45
Aver.	5.77	26.87	56.12	17.23	2.23

As the weight of coal received from each colliery for each month was known, the following analyses of the mixture received at the wash plant for each month were calculated, and are as follows:—

Month.	Moist.	Vol. and Comb. Mat.	Fix. Carb.	Ash.	Sulphur.
1	5.62	27.71	56.48	15.93	2.17
2	5.61	27.82	56.50	15.98	2.18
3	5.67	27.75	56.54	15.83	2.16
4	5.69	27.40	56.31	16.53	2.19
5	5.68	27.25	56.28	16.72	2.20
Aver.	5.65	27.56	56.43	16.19	2.18

The average analyses of the washed coal resulting from the washing of the above coal, and covering the same period, are as follows:—

Month.	Moist.	Vol. and Comb. Mat.	Fix. Carb.	Ash.	Sulphur.
1	16.25	34.86	60.58	4.52	1.27
2	13.87	35.01	61.00	3.96	1.25
3	11.95	38.20	58.14	3.66	1.45
4	14.01	35.70	58.56	5.80	1.74
5	11.00	35.92	59.36	4.72	1.75
Aver.	13.42	35.94	59.53	4.53	1.50

Thus it is seen that the average reduction for the five months has been from 16.19 per cent. to 4.53 per cent. in ash, or 72 per cent., and in sulphur from 2.18 per cent. to 1.50 per cent., over 30 per cent. reduction. It might be said in regard to the above figures that the greater quantity of ash in the coal in the last two months was due to the increased percentage of "C." coal used. This coal was not run over a picking belt since that colliery was newly opened, and was not as well equipped as the other collieries.

The most prominent feature of the coal treated, a soft bituminous variety, is the high percentage of volatile and combustible matter which is typical of the Cape Breton coal measures. The coal mixture also has a high percentage of sulphur and more ash than is consistent with economy. Most of the impurity is present in the form of slate, there being only a small percentage of bone coal. The following analysis is that of the impurity which sinks in a calcium chloride solution of 1.35 specific gravity.

$Fe S_2$	13.64	
$Si O_2$	28.50	combined
Al_2O_3	17.59	as slate.
Ca O	6.74	
$Mn Co_3$	2.91	
Mg O	0.44	
Chem. Comb. H_2O	15.10	
Carbonaceous matter	14.80	partly bone coal.
	99.72	

About one-half of the sulphur contained exists as iron pyrites ($Fe S_2$), which seems to occur evenly and uniformly distributed through the coal and bone in the form of small nodules, leafy formations between the layers, and as a series of particles in size between 80 and 100 mesh; the remainder of the sulphur is present as organic sulphur. It is impossible to get rid of this latter portion by any specific gravity method of separation, and it is called the fixed sulphur.

The following are the specific gravities of the coal constituents:—

Slate	3.83
Coal	1.27
Splint or bone	1.50
Pyrite	4.80

In order to determine the best possible separation that can be effected with the coal in question by means of a specific gravity method, the following experiment has been made: A calcium chloride solution of slightly higher specific gravity than that of coal, and less than that of the other constituents, was put into a glass jar of about three-quarter-gallon capacity; to this solution was added a weighed quantity of coal of the same size as supplied to the jigs. The contents were stirred briskly and allowed to settle. The sample was now found to be divided into two portions. All particles of a specific gravity less than that of the solution had floated while all the particles heavier than that had gone to the bottom. Between these two layers there remained suspended in solution a small proportion of the particles whose specific gravity was about that of the solution. The floating and sinking portions were separately removed, washed free from the solution, weighed, and analyzed. From the data thus obtained we calculate the purity and yield of the floating portion of the washed coal obtainable. This is the simplest and most effective coal washing operation that can be performed, and the results of this experiment determine absolutely for any coal the maximum purity of the washed coal obtainable from it by any washing process. The calcium chloride solution used was of 1.35 specific gravity, which was found best suited for this coal.

The results of a series of such experiments conducted at the same time as the analysis already given, are as follows:—

Average composition of float on $Ca Cl_2$ solution 1.35 sp. gr.:

Vol. and Com. Mat.	Fix. Carb.	Ash.	Sulphur.
36.67	59.92	3.41	121

From these figures we learn that the coal treated had a fixed ash of 3.41 per cent., and 1.21 per cent. of fixed sulphur. Consequently the plant washed the large tonnage of coal treated in the five months to within one and one-quarter per cent. of the best possible reduction in ash, and to within a third of one per cent. (0.3) of the best possible reduction in sulphur.

The loss in washing for the large amount of coal treated has been 13 per cent. plus 8 per cent., which is the difference in moisture, a total of some 21 per cent., and of this the impurity removed as ash and sulphur is 12 per cent., which leaves an actual coal loss of about 9 per cent. in the process.

The slate resulting from the washing process from the coarse jigs contains about 25 per cent. of good coal, and is therefore lifted by bucket elevator to the top of the jigs and re-washed in No. 4 coarse jig with the following results:—

	Original slate.	Washed coal from slate.	Slate re-washed contans about 13% impure coal.
Vol. and Com. Mat.	21.80	30.59	19.10
Fix. Carb.	37.10	51.61	24.40
Ash	41.10	17.18	50.50
Sulphur	4.06	2.79	9.07

This re-washed product is used about the plant under such boilers as are worked below their rated capacity.

A point of interest about the washer is the ingenious method of disposing of the slate, which was introduced last spring by Mr. John Preston, the engineer who had supervision of this department. Hitherto the slate had been elevated to a bin in the storage tower, from whence, at proper intervals, it was removed on cars to a convenient dumping place. The present scheme is quite simple, and consists in flushing the slate from the jigs directly to the sea.

The following description of the equipment will explain the method in detail: An 8-inch pipe has been laid from the shore to the central condensing plant at the colliery where the washer is situated, and through it a 7-inch Gwynne centrifugal pump supplies salt water for condensing purposes. This pump has a rated capacity of 1,200 imperial gallons per minute at 900 revolutions per minute, and is directly connected to a 50 horsepower, 3-phase, 60-cycle, 220-volt induction motor located at the seashore. The condenser is a 12 and 17x19x15 Worthington jet condenser, arranged to take steam from a Walker double compound compressor, a tandem compound fan engine, a tandem compound haulage engine, and a simple cylinder haulage engine; the four engines totalling up about 1,500 horsepower. The discharge pipe of the 7-inch centrifugal pump, which has a lift of 50 feet, is directly connected to the suction pipe of the air pump of the condenser. The air pump discharge delivers the salt water, after condensing the steam from the engines, to a 6-inch cast iron pipe, which passes through the wash plant, and is used for conveying the slate from the wash plant to the cliff, a distance of about 700 feet.

A valve controlling the amount of water supplied to this pipe is placed between the air pump discharge and the square hopper through which the slate enters the

pipe, with an overflow ahead of it which carries away the difference between the amount of water delivered and the amount required. The supply valve is kept sufficiently open to allow the water to half fill the hopper. The pipe is laid on a downward grade, varying from one to four per cent., towards the cliff. At the cliff, which it overhangs, there is a vertical leg about 26 feet long, the effect of the latter is to give an hydraulic gradient to the entire line sufficient to cause a flow of about 600 or 700 gallons per minute, when the pipe runs full bore; the resultant velocity causes all slaty material to be easily carried through the pipe.

In order to keep foreign material, such as bolts and spikes, from getting into the pipe and plugging it up, it has been found necessary to fit the hopper with a special grating, which consists of a cast iron plate, about six inches thick, perforated with 2½-inch diamond-shaped holes, the holes being V-shaped or zigzag in vertical section; this construction allows any round or square material up to about 1½ inches in diameter to pass through it, but will not allow any material having a length of over 2½ inches to pass. Further precautions are taken to cope with clogging in the line by having special oblong openings cast in the pipe every few hundred feet apart. These openings have covers screwed on, which can be removed at will. Should the pipe become clogged, lengths of small pipe, such as are commonly kept in stock, are coupled together and inserted into the opening immediately below the clog, and forced against the obstruction, the water pressure being kept in the meantime on the remainder of the pipe. Once started, the rush of water quickly clears the pipe.

Since the amount of water used for flushing purposes is already required by the colliery for condensing, the colliery and wash plant divide the pumping charges equally, and the cost of disposing of the slate by this method is very low.

The figures of a typical analysis of the coke from the washed coal may prove interesting. Such an analysis would be as follows:—

Moist.	Vol. and Com. Mat.	Fix. Carb.	Ash.	Sulphur.
12.5	2.25	90.50	7.25	1.22

Thus it will be seen that this plant renders possible the manufacture of a coke which is eminently suitable for use in the iron blast furnace from a coal which unwashed would be unsuitable, and in addition utilizes for this purpose the less desirable, from the fuel point of view, portion of the coal, that is, the screenings.

The writer wishes to acknowledge his indebtedness to the management of the Nova Scotia Steel and Coal Company for permission to use the information given and for access to the records of their chemist. The author is, however, responsible for the preparation of the average analyses and for the conclusions drawn.

INAUGURAL ADDRESS.

By the President of the C. M. and M. Society of South Africa.

(*Continued from last issue.*)

Apprenticeship to Mining.—For those who would take up the work of actual underground mining as a means of livelihood, the system of apprenticeship, as started by the Association of Mine Managers, would seem to be an excellent scheme, and it was with great regret that I learnt from some remarks made by Mr. Laen Carter at one of our recent meetings, that "so far it had not been a success, and that at the present time there are very few apprentices underground." This is not as it should be. Means must be found to induce young men to submit themselves to a regular and thorough apprenticeship below ground, as is done by mechanics above ground, so that when a youth having duly served his term, applies for work as a full-fledged miner, the employer will have a guarantee that the applicant does possess a knowledge of the work he wishes to undertake, and to such as take a serious view of mining work and wish to learn thoroughly what is most necessarily, namely, the theory as well as the practice of the work, I would commend the evening classes in mining, which are held at the Transvaal University College, where the miner is taught how to work intelligently, and thus benefit himself, the mine, and also his fellow workmen. Under the new scheme of the Mine Managers' Association an inducement is held out to apprentices to attend these classes, which I find, on enquiry, have a large membership, and which are attended by men coming from far distant parts of the Rand, showing at the same time the attraction of the classes and the keenness of the students. The youth of this country has to learn to appreciate the fact that if it wishes to take a proper part in the development of the resources of this land it must take measures to submit to a course of study, not alone in one particular subject, but in a general knowledge of science, and to the youth I would say, the means are at hand, make use of them.

I look to the Metallurgical Trials' Committee, which has lately been formed under the aegis of the various mining houses, for much assistance to the mining and metallurgical world. Co-operation of this nature will permit of far fuller and more practical investigation of the merits of any invention or improvement than would otherwise be the case, and I am sure that all those who have thought out improvements, which they are individually unable to have tested or experimented upon, will note the constitution of this Committee with pleasure, and will not be afraid to lay their ideas before the representatives, as I am confident that all trials made will be carried out in the most thorough manner.

Agriculture and Agricultural Chemistry.—There is little question that, apart from the mining industry, which is, undoubtedly, at the present time the staple industry of the country, there are enormous possibilities in the direction of agriculture, and owing to the many varied natures and constituents of the soils to be dealt with, the problems of properly dressing and manuring the land will provide much work for the chemist, without whose aid I fear those who engage in the farming industry will be but floundering in the dark. Those who read that most interesting production, the Transvaal Agricultural Journal (which I may state is free to every citizen of the Transvaal for the asking), will appreciate the great amount of work which has been done in every branch of agriculture by those employed on the Government farms, and I trust that our Government will always realize the great value of the various researches which have been made in the past, and the value of which will perhaps be more apparent in the future, to those engaged in agricultural pursuits. We know that there is a prevalence of a great number of various description of pests, the occurrence of which dishearten the farmer and often indeed stultify his efforts, but I am sure that by perseverance and careful study the difficulties and dan-

gers from this cause will eventually disappear, and in the attainment of this end the chemist will figure largely. I again venture to hope that our Government will recognize the great work which has already been done, and which still has to be done, and will give every encouragement to foster scientific investigations, and the work of the chemist in its application to the benefit of what must become one of the great industries of this vast country with its many and varied conditions of climate and soils.

South Africa should, undoubtedly, be in a position to become a country absolutely self-supporting in every respect. The question of irrigation and the proper conservation of water is one which may rightly and safely be left in the hands of our brother scientists, the engineers.

We have as a lesson in possibilities our marvellous gold industry, and in this respect I cannot do better than refer to the words of that eminent financier, Herr Dernburg, who recently visited us. In the course of a most instructive and eloquent speech he stated that there was a time when the standard of currency was greatly exercising the minds of financial men in the great centres of the world, the question being whether the standard should be gold or silver. At that time arose the Goldsmiths of the Transvaal, the output from which settled the question once and for all; it was to be gold. I doubt if this important fact had ever before been made patent to the world (outside the world of financial men), and I take it to be a happy augury that if South Africa has been able to settle this important question she will be able to settle many others of as great importance to the welfare of human-kind.

Our Society continues to be on terms of the greatest amity with the kindred societies; this is much evidenced by the fact that some of our members have been invited by the Transvaal Institute of Mechanical Engineers to assist upon a committee, which that institution has formed for the purpose of establishing South African standards for strengths of materials, etc.

Our Society is now widely represented by members in all parts of the world, but there is still much further scope for its usefulness, and I trust that those who have been and will be appointed (under the new scheme, which you have approved of and which strikes me as such an excellent one) "as Corresponding Members of Council" will do their utmost to further our interests by bringing in new members, and by obtaining for our information and instruction, papers upon the many and varied subjects which come under the scope of our work, and also help us by contributing to our discussions. While on the matter of discussions, I cannot too strongly urge upon members the value of the fullest possible discussion upon a paper, as by this means we learn the views of individuals, and obtain the results of the experience of many hard and practical workers who may not feel able to write original papers, but whose attention and interest is awakened by statements made in papers written by others, which statements they may be able to confirm or otherwise from their own experiences, and thus the discussion becomes as valuable as the original paper. I would also urge our members to come forward with descriptions and records of processes and methods which they may have tried and not found to be successes. The information contained in a record of trials which have proved failures is of the greatest value to the metallurgical world.

The reduction in working costs, improvements in plants, and higher efficiency in the mining and metallurgical departments, as well as better extraction, have brought large bodies of ore, which were in former times classed as "unpayable," either within, or very nearly within the "payable" class, and it must be the aim of all the members of our Society, both the mining and the metallurgical members, to take advantage of all existing improvements and to endeavor to devise new ones in order to assist in bringing down the general costs of production to such a point that aided, we may hope, by still better extraction of the gold, it shall be possible to see a profit where but loss existed before. In this endeavor we must work hand in hand with our good friends the kindred societies of engineers, whose aims run on lines parallel to our own. Thus can we do our portion towards making it commercially possible to open up new lines and to reopen many old ones, to the end that the industry may be able to sustain a larger white population, and that by such means the burden of those who are now suffering so severely from want of employment may be lightened, and prosperity may again reign in this country.

COAL BRIQUETTING IN 1907.

By Edward W. Parker.

From Advance Chapter Mineral Resources of the United States.

That considerable progress was made in the development of a briquetting industry in the United States in 1907 is shown by the reports of operations made to the Geological Survey for that year. There were eleven plants in actual operation during 1907, although one of these, that of the Pittsburg Coal Mining Company, at Pittsburg Landing, Cal., was burned in July and had not been rebuilt up to the close of the year. The total production of briquets, as reported to the Survey, amounted to 66,524 short tons, having a value at the plants of $258,426. When compared with the development of this industry in Germany (in which country the production of briquets in 1906 amounted to about 16,000,000 short tons), the production in the United States appears insignificant, but it is of importance as indicating that a beginning has been made, and with the success of the established plants demonstrated and the gradual education of consumers in the advantages of briquets for efficiency, ease of handling, and cleanliness, rapid progress should be made in this industry during the next few years.

As constant dropping of water wears away the stone, so the constant agitation of this subject has begun to show its effect, and the rock of opposition, or at least of inaction, is being worn away. There can be little doubt that the interest aroused through calling attention to the waste of that part of the country's natural resources, represented by the nonuse of the slack and culm pro-

duced in our coal-mining operations, and the aggressive policy of President Roosevelt in seeking to throw light upon it and to correct the abuses into which we have largely unconsciously fallen, are to a great extent responsible for the present prospect of a development of coal briquetting, as an important industry in the United States. It may not be long before the governments of the States, under whose jurisdiction the matter comes, will enact legislation against the accumulation of slack and culm heaps or their useless destruction by burning, and prohibit this waste, as they have in some cases interdicted the waste of natural gas.

Legislation which would prohibit "shooting from the solid" at mines, when the slack coal is not a marketable product, and which would provide penalties for excessive use of powder, would have, as one result, a larger percentage of lump coal, and thus, in part at least, enable operators to assume the additional expense involved in the briquetting of such slack coal as is unavoidably produced.

There were eleven coal briquetting plants in the United States, each manufacturing briquets, during 1907. The location of these plants and the character of the fuel and binder used in the operations are as follows:

Arizona Copper Company, Clifton, Ariz.—This company uses bituminous coal, mined in New Mexico, with an asphaltic pitch made from California crude petroleum. The briquets weigh aproximately 4 pounds each and are used under the boilers of the company's plant. The briquetting machine is of English design and is described in the United States Geological Survey Bulletin 316, published in 1907. The capacity of the machine is 24 tons in a day of ten hours.

Western Fuel Company, Oakland, Cal.—This plant, which is also described in Bulletin 316, operates on bituminous coal slack or screenigs with asphaltic pitch, with proportions of 90 per cent. of coal and 10 per cent. of binder. The capacity of the machine is 60 tons in a day of ten hours. The operations of the company were begun in June, 1905. The briquets are cubical in shape, with rounded edges, and weigh approximately 10 ounces each. They are used principally for domestic purposes.

Pittsburg Coal Mining Company, Pittsburg Landing, Cal.—This plant was put into operation during the first six months of 1907, but was burned in July. It was operated upon screenings from the coal yards of San Francisco, using asphaltic pitch as a binder in the proportions of 92 per cent. of coal and 8 per cent. of pitch. The briquets are of semicylindrical pattern, weighing about 8 ounces each and are used principally for domestic purposes.

Indianapolis, Briquetting Company, Indianapolis, Ind.—This company began installing briquetting machinery in 1906 and commenced operations in November, 1907, using 92 per cent. bituminous coal slack and 8 per cent. of coal-tar pitch. The briquets are of cylindrical shape, weighing 5 ounces when intended for domestic purposes. Larger sized briquets can be made, if desired, the capacity of the machine depending upon the size of the briquets.

Semet-Solvay Company, Detroit, Mich.—The Briquetting plant of the Semet-Solvay Company, located at Delray, Mich., is operated in connection with the plant of the Semet-Solvay by-product coke ovens at that place and is intended primarily to make available for use the coke "breeze" produced at the ovens. As originally designed (early in 1905) this plant contained a Johnson (English) briquetting press, but the product, on account of the large size of the briquets, was not found adapted to the market and a Mashek type of press was substituted. The new machine was started in August, 1907. Another machine, producing the eggette or ovoid-shaped briquet, has been purchased but has not been delivered. When the new machine is installed the plant will have a capacity of nearly 20 tons an hour. The present practice consists in using a mixture of 50 to 75 per cent. of bituminous coal slack and 50 to 25 per cent. of coke breeze. From 91 to 95 per cent. of this mixture is used with 9 to 5 per cent. of coal tar pitch. The briquets weigh about 2 ounces each.

Western Coalette Fuel Company, Kansas City, Mo.—This company is operating a Renfrow machine, the type of which, described in Bulletin 316, formed a part of the equipment of the Geological Survey coal-testing plant at St. Louis, Mo., subsequent to the exposition period and later at the Jamestown Exposition. The machine was installed in Kansis City in April, 1907, and is operating upon semi-anthracite slack from Arkansas and Oklahoma and bituminous coal slack from Kansas and Missouri, using coal-tar pitch as a binder in proportions of 94 per cent. of coal and 6 per cent. of binder. The briquets are cylindrical in shape with convex ends, weighing approximately 14 ounces. They are intended for household, locomotive, and stationary boiler use. The capacity of the machine, of which there was only one installed at the close of 1907, is 8 tons per hour. The operations during the year were largely of an experimental character and considerable construction work was caried on at the same time.

D. Grieme Coal Company, foot of West Forty-seventh Street, New York, N.Y.—This plant, among those described in Bulletin 316, was put into operation in October, 1907. The press is of Mashek design and makes a small, rectangular, convex briquet which is intended entirely for domestic purposes. They weigh aproximately 2 ounces each. The coal used is anthracite No. 3 buckwheat and culm with coal-tar pitch as a binder, the proportions being 93 to 94 per cent. of coal and 6 to 7 per cent. of binder. The capacity of the machine is rated at 13 tons of briquets per hour.

The National Fuel Briquette Machinery Company, foot of Court Street, Brooklyn, N.Y.—This plant is also described in Bulletin 316, and consists of a Belgian type press manufacturing small eggettes which weigh less than 2 ounces each. It is operated on anthracite culm and coal-tar pitch with proportions of 95 per cent. of coal to 5 per cent. of pitch. The eggettes are intended primarily for household use, and the principal market is in the domestic trade of Brooklyn. They are also used to some extent for stationary boilers. The capacity of the machine is rated at 6 tons per hour.

The Scranton Anthracite Briquette Company, Dickson City, Pa.—This plant was the largest producer of briquets in the United States during 1907, although it was operated only seven months during the year. The plant is located adjacent to one of the Delaware, Lackawanna and Western mines, near Dickson City, and the briquets are used on the locomotives of that railroad. Anthracite culm is used exclusively with a patented binder of which coal-tar pitch is a principal ingredient. The company prefers not to publish the proportions of coal and pitch used. The briquets are of eggette pattern, weighing about 8 ounces each. During the year the company was engaged in enlarging its plant, and for this reason operations were carried on during only seven months of the year. When the extension work is com-

pleted the company expects to have a capacity of 10,000 or 12,000 tons of briquets per month.

The Briquette Coal Company, Staten Island, N.Y.—This plant, which was completed in July, 1906, and which was briefly described in Bulletin 316, consists of two presses, one of German type and one of Belgian type, the briquets made in the former weighing approximately 1 pound each and those in the Belgian about 4 ounces each. The machines have a capacity of respectively 4½ to 7½ tons per hour. The plant is operated on a mixture of anthracite culm and bituminous slack coal and also on anthracite alone with a binder, of which coal-tar pitch is the basis. The company does not care to give details as to binder or the percentages used.

The United Gas Improvement Company, Point Breeze, Philadelphia, Pa.—As stated in the report on the Coal Briquetting Industry in 1906, published in Bulletin 316, this plant is operated primarily for the purpose of utilizing the breeze produced at the gas works of the company. It is found advantageous to mix the coke breeze with anthracite culm and bituminous slack in addition to the binding material. The average mixture is 42 per cent. anthracite culm, 13 per cent. bituminous slack, 35 per cent. coke breeze, and 10 per cent. water-gas pitch. The briquets weigh approximately 5 ounces each, are of eggette pattern, and are charged into retorts and used in the manufacture of water gas. There are two machines in the plant, both of Belgian type, which have a capacity of 50 tons per day.

In addition to the preceding list of plants, all of which were in operation in 1907, the following companies have been organized for the purpose of establishing coal-briquetting plants. This list does not include any of the names published in Bulletin 316 which have passed out of existence or from which no replies were received from inquiries sent asking for information regarding the operations of the plants during 1907:

The Standard Fuel Company, Birmingham, Ala.—A new company, incorporated in 1907; it did not produce any commercial briquets during the year.

The United States Briquetting Company, San Francisco, Cal.—This company was organized for the purpose of exploiting a process for briquetting peat with California petroleum. All of the work so far has been of an experimental character.

North American Coal Briquetting Company, 81 New Street, New York, N.Y.—This company was organized for exploiting the Forst briquetting process, the main feature of which consists in the material to be used as binder. It consists principally of coal-tar pitch, but the other ingredients of the binding material are kept secret and the process is a patented one. The company has not yet begun operation on a commercial scale.

Zwoyer Fuel Company, 60 Wall Street, New York, N.Y.—The plant of this company, which is described in Bulletin 316, was removed from Brooklyn, N.Y., to Perth Amboy, N.J., during 1907, and was not operated during the year.

American Briquetting and Manufacturing Company, Williston, N. Dak.—This company was organized for the purpose of briquetting North Dakota lignite, using 94 per cent. of lignite and 6 per cent. of binder composed of flax-fiber sirup and rosin. The briquets are to be made in large sizes, weighing 2 pounds 8 ounces each. It is estimated that the machine would have a capacity of 9 tons per hour. It is anticipated that the plant will be in operation during 1908, manufacturing briquets intended for household purposes and for stationary boilers.

Washington Coal Briquetting Company, Seattle, Wash.—This company was incorporated in 1907 for the briquetting of slack coals from the coal mines of the State. The plant had not been completed at the close of 1907.

The Coal-Briquette Machine Company, Oshkosh, Wis.—This company organized in 1907 and expected to be in operation during 1908. It is manufacturing some briquets out of anthracite and bituminous coal and lignite in an experimental way. The briquets are cylindrical in shape and weigh, approximately, 12 ounces each. The capacity of the machine is rated at 48 tons a day.

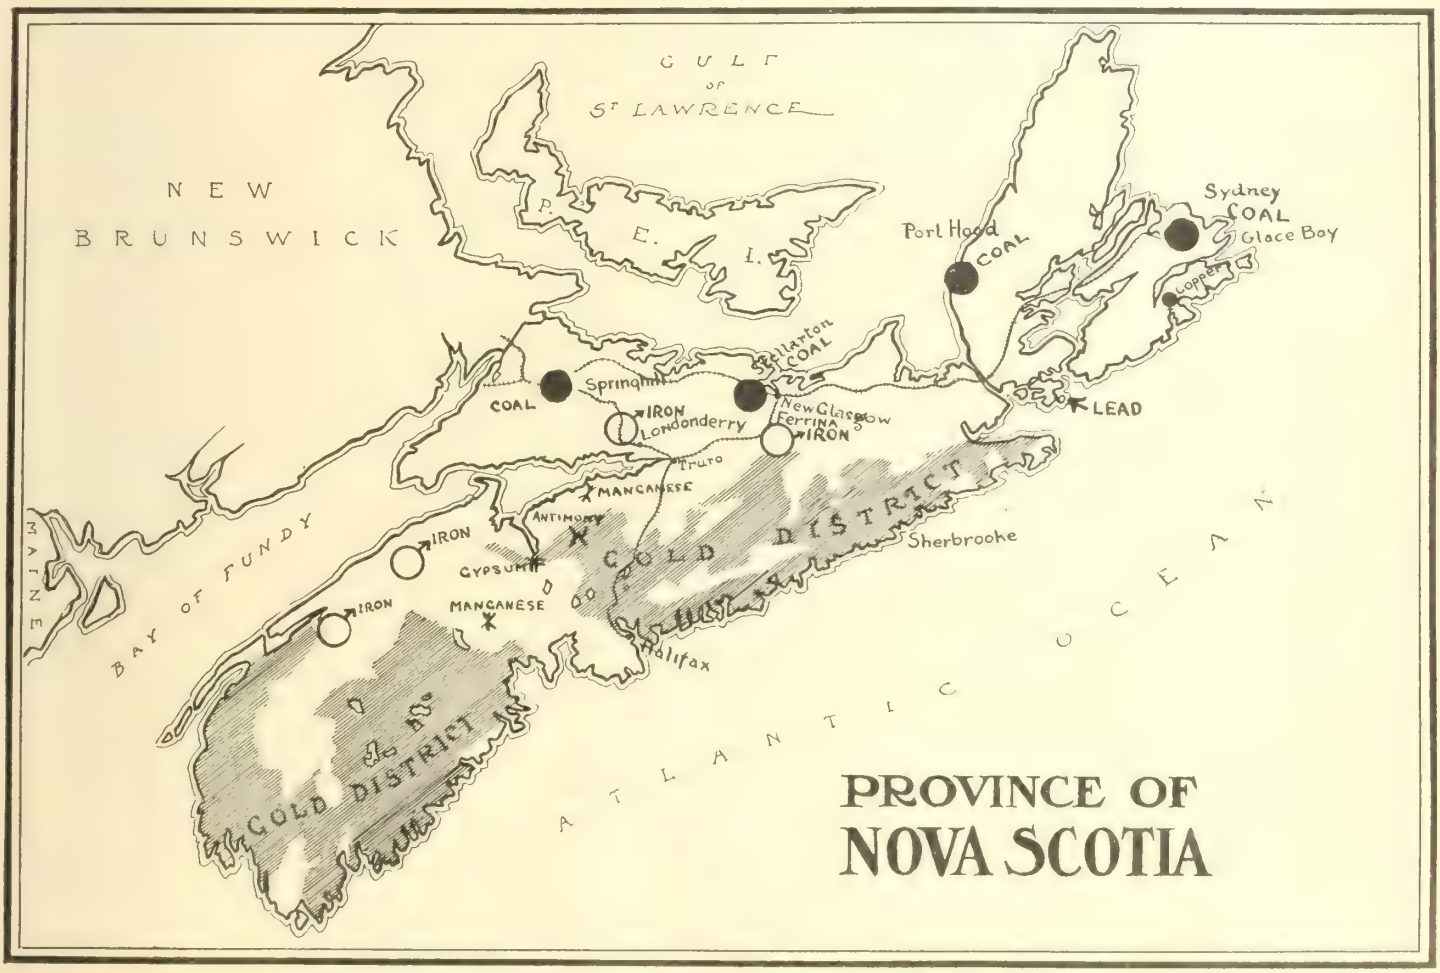
American Lignite Briquette Company, Rockdale, Tex.—This company, of which Mr. J. J. Olsen, of San Antonio, is president, was organized in 1907 for the purpose of briquetting lignite mined at Rockdale. The company expected to be in operation during the summer of 1908.

United States Coal Manufacturing Company, 1339 Arch Street, Philadelphia, Pa.—This company has manufactured some briquets in an experimental manner, but at the close of 1907 had not produced any on a commercial scale. The briquets are of triangular shape, of small size, and intended for domestic use. The character of the binder and the proportion of binder and coal used are kept secret by the company. High calorific value, easy ignition, complete combustion, and absence of clinkering are merits claimed for these briquets.

R. B. Metcalf, Portsmouth, R.I.—Mr. Metcalf, who has done considerable experimental work in the briquetting of Rhode Island anthracite, had not begun the manufacturing of briquets on a commercial scale at the close of 1907, although he expected to have a plant in operation before the close of 1908.

When a few years ago, the alloy of aluminum with 6 per cent. of copper for use for various naval purposes did not give the complete satisfaction that was expected of it, the aluminum then available had not the degree of purity which now obtains. Aluminum manufacturers then set to work to improve their methods of manufacture; they now produce aluminum of a high degree of purity, and they are quite as eager in recommending the use of this pure aluminum in alloys as its ing of a French aluminum manufacturer to the effect use alone for different engineering purposes. The say- that "the future of aluminum lies upon the water." is more true now than it ever has been. Seeing also the very great efforts which are being made at the present time in the construction of dirigible balloons and aeroplanes, its future is likely to be further extended still, while in the numerous branches of the electric industry the use of aluminum is steadily developing day by day."

The marble output of the United States in 1907 was valued at $7,837,685. Vermont marble is used for outside building and for monumental work, also for interior decorations, for electric work, mosaic work, etc., and is sold principally as dressed stone. Vermont produced about 1,450,000 cubit feet, 58.65 per cent. of the entire output.



GOLD MINING AT WAVERLEY, N.S., FIFTY-TWO YEARS AGO.

The late Sir J. W. Dawson visited the Waverley gold mines in 1866, six or seven years after the first discovery of the metal in Nova Scotia. Sir William, then plain Mr. Dawson, incorporated a note this visit in his book, "Acadian Geology."

The Waverley veins were at that time the most extensively worked in Nova Scotia. The ore was extracted in large open cuts along the strike of the vein, and was hoisted by horse "gins." The deepest pit was 225 feet. Dawson noted in this pit that the vein consisted of compact grayish-white quartz, varying in thickness from four feet to six inches, but having an ordinary width of about two feet. The footwall, he states, consists of coarse gray slate, with small cross veins of quartz, the hanging wall of hard gray quartzite presenting a waved and crumpled surface. "The quartz," he remarks, "has a laminated or banded appearance, and the gold seems to be most abundant near the walls; though visible gold is rare in this vein at present, the greater part being in a minutely disseminated and invisible state. The superintendent of one of the mines informed me that the thicker portions of the vein afforded scarcely more gold than the thinner portions, and that the gold is most abundant near the hanging wall." This particular vein was known then, as it is now, by the name of "Tudor."

Mr. Dawson expresses admiration for the equipment of the "German" mine at Waverly. The quartz from this vein, he tells us, "is crushed in an admirable stamping mill, worked by steam, and at present having sixteen stamps, though capable of being increased to twice that number." The completeness of the apparatus "for the *subsequent* amalgamation and distillation necessary to obtain the gold," is commented upon. The problem of recovering the gold from the "metallic sulphurets" was even at that early date a subject of practical interest. Dawson does not, much to our regret, go into details on this point. Battery amalgation was not in vogue. Only the gold caught on the plates was recovered.

The yield in those days was heavy. Waverly ore averaged more than one ounce of gold to the ton, despite crude and wasteful methods. Five mills, four worked by steam, and one by water power, were in operation. In 1865 the Waverly district yielded 13,102 ounces. The

WAVERLEY LIES ABOUT TWELVE MILES FROM HALIFAX ON THE I. C. RY.

rate of return per man employed was $895 per annum.

In view of the later history of gold mining in Nova Scotia, Dawson's recommendations as to mining methods and government assistance have something of a prophetic air. Summing up the situation (1866) he points out that the veins then opened were not worked up to their highest point of profit. Even in the larger mines, like those of Waverly, no vertical shafts had been sunk on the veins.

"The desire to make the work [immediately] remunerative as it proceeds has induced all the companies to sink on the slope of the veins,and to conduct the works on the cheapest possible plan." Dawson then expresses a strong conviction that, considering the regularity and extent of the veins, were vertical shafts sunk to a great depth and regular mining in the Cornish plan pursued, the initial outlay would be more than repaid by increased production. Some of the veins then worked had improved with depth; others showed impoverishment. But Dawson affirmed that there was no sound reason to doubt that the principal veins opened continued profitable to great depths. In his opinion it would have repaid the Provincial Government to grant special privileges to such companies as were willing to expend sufficient capital to open mines on a large scale.

Some conception of the interest taken in gold mining five years after the first rush occurred is obtainable from the fact that in 1865 there were 38 stamp-mills in commission. Twenty-seven of these were run by steam, 11 by water power, 30,963 tons of ore crushed yielded 24,162 ounces of gold. The average yield was 15 dwt. 14 grains per ton. The maximum yield, evidently from a small parcel of ore, was reported from Wine Harbour. This was 87 ounces per ton. The average yield per man employed was $669.41.

UNIT MINING AREAS OF DIFFERENT COUNTRIES.

There is great divergence in the unit mining areas of different countries. For information of this sort, Hatch and Valentine's "Mining Tables" is a ready source of reference.

Some of the following statements are not revised to date, but in the main they are correct. The mining area of British Columbia is a rectangular claim not exceeding 1,500 feet in length or width, measured horizontally, with no extralateral right. The vertical planes in which the boundaries lie, projected downward define the underground rights.

The gold and silver mining area of Nova Scotia is a rectangle measuring 250 feet by 150 feet, laid off with the shorter sides running east and west. 100 is the maximum that can be taken up by one person. For the mining of other minerals an area of five square miles, not exceeding 2 1-2 miles in length, may be granted.

400 acres is the amount of mining territory that one person may acquire in Quebec, although by special Order-in-Council 1,000 acres may be taken.

For gold and silver the New Brunswick area is practically the same as in Nova Scotia.

The unit area for vein mining in the United States is the claim of 1,500 feet along the strike of the vein by 600 feet in width. By virtue of the "law of the apex" extra-lateral right allows the vein to be followed beyond the vertical plane in which the surface boundaries lie.

In Mexico the unit area for the mining of all metals, precious stones, rock-salt, and sulphur, is the pertenencia, which is a solid block of unlimited depth, defined above ground by that part of the surface which in horizontal projection gives a square, each side of which measures 100 metres; and bounded underground by the four vertical planes corresponding to the sides of the said square.

The Transvaal claim, for vein and reef mining, has an area of 60,000 square Cape feet. (One Cape foot equals 1.033 British). Where practicable the claim is a rectangle in form, measuring 150 Cape feet along the strike by 400 Cape feet in a direction at right angles to the strike.

SETTLING SLIMES IN CYANIDE TREATMENT.

"The author describes a process which has given remarkable results, both in the completeness of the separation effected and in the small proportion of liquid carried off by the solid matter, which is removed as it reaches the bottom of the tank. This is of inverted pyramidal shape, and connects at the bottom through an 8-in. square aperture with a closed box in which a 10-in. belt is made to travel slowly. The method may be applied in practice in either of two ways. First, as in intermittent process in which the belt discharge of solids would be delivered into a second similar tank where a weak solution or wash water could be sprayed on to the belt to loosen and disintegrate the slime; or a mixer may effect this purpose. After removal of the required proportion of solids the solution would be withdrawn to the original level and a second charge introduced. Secondly, the introduction of a suction filter near to the surface of the liquid in the separator, permits of a continuous process being carried on. The percentage of moisture in the discharge is inversely as the proportion of solids in the separator charge, and the first portions of a discharge from any given separator charge are always better than the succeeding portions, hence the density of the separator charge is maintained as its initial figure, the moisture in the discharge would be kept at a minimum and the rate of discharge increased. By an automatic periodical cutting off of the suction and application of small back pressure the filter screen is kept clear from caked slime and clear liquid is continually drawn from a pulp of sp. gr. 1.4. The belt and suction must be so correlated that the solids discharged are proportionate to the liquid sucked out, and the discharge from a pulp of the density stated will uniformly contain about only 22.5 per cent. of moisture. If there be two suction pipes with screens they are kept clear by back pressure being applied alternately to each. The continued use of screen suction would not be possible unless the solids were being extracted by the conveyor belt. The procedure in the wash settlers is practically the same. The solids are washed off the belt by precipitated solution and water, and the suctions withdraw an equal amount of liquid, which is passed through the extractor boxes and returned from the sump. In other processes completeness of washing is dependent on time and capacity of plant, as each instalment of slime is taken separately and washed solution passed through it as long as economically possible, when it must be removed, whether well washed or not, to make room for the next

instalment; but in this method continuity is unimpeded and slimes may be washed out with any reasonable quantity of weak solution without affecting the time of treatment—the only factor affected being the capacity of the extractor boxes.

The advantages of this method are: (1) Absence of pumps, carrying machinery and complicated appliances; (2) the separation of sands from slime is not called for, and thus disadvantages attendant on dealing with such classes of material as depend on close classification are obviated; (3) it is possible to wash to the best advantage and thus reduce the loss by residual moisture; (4) the degree of fineness or uniformity is immaterial; (5) the initial cost is very low, and niceties of adjustment are not requisite; (6) the only limit to the thickness of a charge is the point at which it will not run, and best results are obtained from charges with high percentages of solids; (7) the process may be continuous. The paper is accompanied by diagrams and tables showing the arrangement and the results of working."—Electrochemical and Metallurgical Journal.

ELECTROLYTIC SEPARATION OF NICKEL AND COPPER.

Nickel can be accurately determined by electrolysis of the nitrate, provided (1) no nitrite be present, (2) a sufficient excess of ammonia be added, and (3) a straight wire of passive iron be used as anode. Iron is necessary since platinum anodes are more or less irregularly attacked, and the dissolved platinum is deposited with the nickel. The metals (0.4 to 0.5 gram in all), or compounds containing them, are dissolved in nitric acid, with an excess of 5 c.c. of strong acid. Nitrous acid is expelled by boiling. The volume is made up to 100 c.c., and the copper precipitated by a current of 1 ampere at ordinary temperature. Towards the end of the operation the solution is warmed up to 50 degrees or 60 degrees C. To the bath is now added 80 c.c. of ammonia (s.g. 0.91), the iron wire anode, cleaned in hydrochloric acir and rendered passive in strong nitric, is substituted for the platinum one, the coppered cathode replaced, and the nickel deposited on it by a current of 5 amperes. The current heats the solution to 70 degrees C. When the liquid is decolorized and gas evolution occurs at the cathode, the latter is withdrawn without stoppage of current, and washed, dried, and weighed. After retesting, the deposition of nickel is complete in 55 minutes. The ammonium sulphide test is useless in solutions containing so much free ammonia. Hence the need of retesting.

NEW USE FOR PLASTER OF PARIS.

"Not only is plaster of Paris an excellent flux for melting such materials as washings, grindings, or chips, but it has also the property of removing iron, a fact not generally appreciated. Plaster of Paris when melted fuses to a clear liquid, which has the property of dissolving oxides. Being a heated flux it does not attack the crucible. To use plaster of Paris for melting washings, grindings, or other scrap which contains iron, about 5 lb. are mixed with 100 lb. of the scrap and the whole is melted down. The plaster melts and clears the scrap of the iron. When the whole is thoroughly melted and the metal well stirred the plaster need not be skimmed off. The whole is poured into an ingot mould. When cold, the plaster is easily removed by a blow from a hammer. Frequently it comes away of its own accord. Small quantities of iron may in this way be removed from scrap metals, a good melt being at the same time obtained. Not only is plaster of Paris an excellent flux for melting such materials as washings or grindings, but it has the great advantage of not attacking the crucible. This is not possessed by any other flux."—Indian Engineering.

MINERAL LAWS OF NEWFOUNDLAND.

In the ancient colony it is lawful for any person to search and prospect for minerals, and to prove the existence, value, and extent of minerals therein or thereunder, without first obtaining a license. This liberty, however, is qualified by the provision that such search and prospecting shall be bona fide with a view to obtaining a mining location and lease thereof under the provisions of the Crown Lands Act. No person so searching or prospecting is permitted to remove from the land any greater quantity of ore, mineral, or metal than shall be necessary to be used as samples. The above does not apply to land appropriated or reserved by the Crown.

CANADIAN PLACE NAMES.

Confusion has resulted from the careless naming of localities in Canada. This is felt as much by the mining fraternity as by any other class. To illustrate some of the needless sources of confusion one has but to look through the pages of the Geological Survey Index. Everywhere, in every province, there is duplication of names of towns,, villages, districts, rivers, etc. There are 22 streams known by the name of "Little River." There are five "Eel" rivers and 20 "Black" rivers. And so on. Names of this sort are entirely lacking in charm and meaning.

MINERALS AND WATER SOLUTIONS.

Metals are precipitated from solutions of their salts by natural silicates. Almost equivalent quantities of the bases of the silicates are dissolved at the same time. In these reactions the most common replacing bases are sodium, potassium, magnesium, and calcium. The metals are precipitated as hydroxides or basic salts.

The principal changes in matters pertaining to ore dressing during 1907 were in the direction of modifications of existing processes. Steam stamps are used extensively only in the Lake Superior copper districts. The Harz jig is still acceptable. The Wilfley, Deister, and other such concentrating tables are most used for fine concentration. Suspended Frue vanners have been tried successfully. There is a marked tendency to introduce flotation processes of various types for the concentration of mixed sulphides. Magnetic concentration has advanced rapidly, bot hin efficiency and in scope of application. In Norway and Sweden the concentration of lean magnetites, along with briquetting of the products, has been most successfully carried on. In America the field for this work is opening up rapidly.

BOOK REVIEWS.

Who's Who in Mining and Metallurgy, containing the Records of Mining Engineers and Metallurgists at Home and Abroad, 1908. Founded by George Safford. The Mining Jounral, London.

We have often suffered inconvenience from the fact that until now there has been no published list of British mining engineers and metallurgists. Even in Canada, although in point of numbers our professional mining men are relatively few, it is not always easy to keep track of every member of the fraternity. Both here and in the United States dependence msut be placed upon the membership lists of technical societies and upon personal items in the periodicals. But, it may be because of the superior modesty of our English brethren, as we have long ago given up the attempt to place any but the most prominent engineers of the motherland.

We extend a hearty welcome to "Who's Who." In its pages we may ascertain the present address, the professional qualifications and other pertinent facts concerning Great Britain's mining men.

Naturally there are omissions. These are due, however,fi not to oversight on the part of the editor, but to the indifference of those whose names are not included.

Canadian mining engineers, investors and others will find "Who's Who" a most serviceable volume.

The Mineral Industry: Its Statistics, Technology and Trade during 1907. Edited by Walter Renton Ingalls. Volume XVI. Supplementing volumes I. to XV. 1100pages. Price, $10. Hill Publishing Co., 505 Pearl St., New York, 1908.

The annual volume of "The Mineral Industry" is too well known to need introduction to our readers. This sixteenth annual edition is in many respects an improvement upon its predecessors.

While the mineral industries of the United States are given first place, those of the rest of the world are not neglected. The correlation of data gathered from all over the globe adds largely to the interest of the volume.

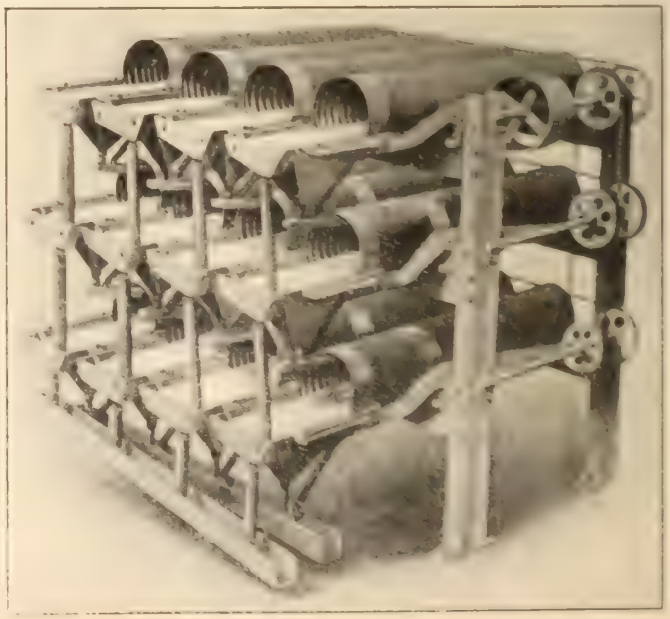
Under title of the minerals in question the volume is devided into chapters each of which is a complete treaties on one branch of the industry. Geological technological and commercial conditions are outlined. Export and import trade is not overlooked.

Statistical tables accmpany each chapter, and figures on the world's mineral output are collected in the last section.

The chapters of most general interest and those describing the advances made during the past year in the study of ore deposits in sampling and assaying and in ore dressing and coal washing.

The list of contributors includes the names of the most brilliant technical writers in America.

In conclusion we must call attention, not for the first time, to the misinformation that vitiates Mr. J. P. Hutchins' description of dredging in the Yukon. It is out of place to reiterate here our criticisms of Mr. Hutchins' attitude. It is also impossible that Mr. Hutchins can have obtained his information at first hand.



For an accurate account of dredging in the Yukon we must refer the reader to two articles by Mr. T. A. Rickard appearing in the Mining and Scientific Press of August 29, and September 12. These articles were written after personal inspection of the dredging territory of the Yukon.

EXCHANGES.

The Engineering Magazine, September, 1908.

Mr. A. Selwyn-Brown's short review of modern development on the metallurgy of lead and zinc is most timely. After disposing briefly of the Huntington and Herberlein, the Carmichael-Bradford, and the Savelsberg processes of wasting and agglomeration, Mr. Selwyn-Brown touches on briquetting concentrates and fine sulphides, sintering, and so on.

But the most important section of the paper is that descriptive of the Macquisten process of flotation, the recent invention of a Glasgow investigator. The Macquisten process differs from the Potter, Delprat, De Bavay, and Elmore processes in employing no chemicals. The sulphide particles are separated from the gangue by utilizing the surface tension of water by means of a simple mechanical device. The operation is based upon the fact that sulphide minerals are positively affected by the surface tension of water while the rock constituents are not so affected. "The surface tension of the water spreads around each sulphide particle like an envelope leaving, probably, between the surfaces of the water and the mineral a bubble of air

large enough to float the sulphide. No envelope is formed around silicates. The water appears to penetrate them and causes them to sink."

The process is conducted in a concentrator composed of a simple cast iron tube, six feet in length and one foot in diameter. Near each end are two tires resting on supporting rollers to enable the tubes to be revolved with little friction. Inside the tubes is a helical groove with an inch and a half pitch running from end to end, as in a bultnut.

"The tube is revolved at the rate of about 30 revolutions per minute. The pulp is screwed through the tube and is so guided by the helical screw groove as to gain the mineral particles repeated opportunities to glide upon the surface of the water. Good concentration can be made in one tube. The inventor's experiments showed, however, that when four tubes were joined in series so that one fed into the next one following, some of the finest particles did not get properly started on the water's surface until they had nearly reached the discharging end of the fourth tube.

"This process has been tried on a larger scale at the Adelaide Mill, Nevada. It was run with an ore composed of chalcopyrite, pyrrhotite, and pyrite with a little blende and galena which previous plants had failed to handle profitably. Each tube successfully treated from 5 to 6 tons of ore per twenty-four hours, concentrating in the ratio of 11 to 1."

Engineering and Mining Journal, October 3, 1908.—The cyanidation of silver ores at Pachuca, Mexico, is written of by Claude T. Rice. The Pachuca ore carries only five grams of gold per kilogram of silver. The ore milled averages about 700 grams silver and 3.5 grams gold per metric ton. The gangue is silicious. The silver occurs as chloride or bromide in the oxidized ore, and mainly as argentite in the unoxidized ore. Some of the ore shows a considerable amount of manganese and a little copper. The ore is completely slimed and air agitation of the cyanide solutions is being introduced.

PERSONAL AND GENERAL.

Mr. H. E. T. Haultain, whose appointment to the chair of mining, Toronto University, is noted on another page, has taken up his new duties.

Mr. Reginald E. Hore has resigned his position as lecturer in the University of Michigan to become lecturer on geology at the School of Mining, Kingston, Ont.

Mr. Aldridge, general manager of the Consolidated Mining and Smelting Co., was in Cobalt recently arranging for the shipment of low-grade ore to the smelter at Trail, B.C.

Mr. Douglas B. Langford, M.I.M.E., who was one of the guests of the Canadian Mining Institute's summer excursion, is at present in Toronto. Mr. Langford will probably spend the winter in Canada.

Prof. A. P. Coleman, of Toronto University, was returned from a two-months' exploration of portions of the Rocky Mountains west of Edmonton hitherto unexplored. An ascent of Mount Robson was undertaken by his party, but after reaching the 11,000-foot level they were forced to abandon the attempt to reach the summit on account of heavy snowfalls.

Mr. E. E. Stockton, of the Auditor-General's Dept., Ottawa, has returned from a visit to the Yukon, where he was engaged for four months on official business. He reports that the gold production of the territory this season will be larger than for many years past, owing to the operations of the Guggenheims, and for the first time the dredges will be busy until the ice forms late in October.

The following is a list of gentlemen elected to membership at a meeting of council held at Victoria, B.C., on September 21st: Members—Alexander Grant, Van Anda, Texada Island, B.C.; J. Edgar McAllister, M.E., Greenwood, B.C.; W. F. McNeill, Canmore, Alta; J. A. Miller, Rossland, B.C.; Geo. Wilkinson, manager South Wellington Coal Mines, Box 286, Nanaimo, B.C.; Mrs. Rosalind Young, 617 Michigan St., Victoria, B.C. Associates—W. Anderson, C.E., Box 666, Rossland, B.C.; H. P. Dickinson, general agent The Giant Powder Co., Box 95, Rossland, B.C.; Chas. F. Law, Vancouver, B.C.; A. B. Mackenzie, Box 222, Rossland, B.C.; Geo. Sheldon-Williams, Box 806, Vancouver, B.C.

Elected to membership at council meeting held at Temagami, Ont., Sept. 6: Members, A. C. Bailey, M.E., box 405, Cobalt, Ont.; Benjamin Browitt, Merritt, B.C.; Freeman I. Daniels, Cobalt, Ont.; Alexander Faulds, Middlesboro', Nicola Valley, B.C.; Ralph W. Foster, M.E., Cobalt, Ont.; Thos. Graham, M.E., Supt. of Mines, Western Fuel Co., Nanaimo, B.C.; H. W. Hardinge, M.E., 43 Exchange Place, New York, N.Y.; J. D. Hurd, M.E., Fernie, B.C.; Jas. Hylands, M.E., Box 18, Cobalt, Ont.; Herbert E. Jackman, M.E., care of Mr. L. A. Hoyt, East Jordan, Mich., U.S.A.; George Johnson, Cobalt, Ont.; M. C. H. Little, M.E., Cobalt, Ont.; J. L. Parker, M.E., care of Tyee Copper Co., Victoria, B.C.; John W. YUKON COAL.

Coal is coming to the front rapidly in Yukon Territory. Last year royalty was paid on 15,433 tons, three times the amount received during the previous year. The price of domestic coal in Dawson is $16 per ton. Tantalus and Coal Creek are the two sources of supply. Coal from the former place is used on the White Pass boats. The coal Creek fuel is used by the electric light plant in Dawson, which is under the same ownership. The Tantalus coal is the better of the two products.

The actual output of the Rand mines last month, as officially announced by the Transvaal Chamber of Mines in London was 587,634 ounces fine. This was 12,366 ounces below the estimates of a week ago as cabled to the Post, and just falls short of the August production, which established high record, having been 587,813 fine ounces.

INDUSTRIAL PAGE.

THE CARNAHAN SYSTEM OF BREAKING ROCK WITH MURPHY DRILL.

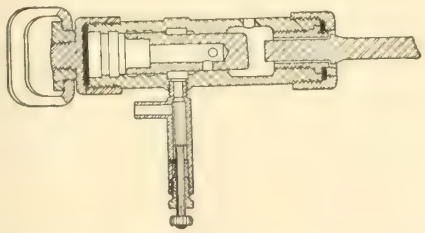
In hard rock one man can easily drill 45 feet a shift with our No. 1 Murphy Drill; 65 feet with a No. 2 and 90 feet with a No. 3, and he can put his holes in to take advantage of the ground the same as if he was doing the work by hand. The extreme simplicity and durability of the Murphy is embodied in the fact that there is but one moving part, and when one of our drills go under ground it goes there to stay. The miner does not lose time bringing them to the top for repairs.

After a little thought all miners will admit the advantages herein claimed for a hand-operated, unmounted drill. It is well established theoretically and practically that rock can be broken more economically by means of shallow holes put in, to take advantage of the ground and shot often, than by filling a heading with deep holes and shooting once a shift.

The reason why a heading is filled with deep holes where either old-fashioned machines are used, is because it takes so much time to set the machine up and take it down. The loss in time being enormous.

It is not practical to set up and take down a mounted drill twice or oftener a shift, as one cannot spend all his time in this way; a little time must be allowed for drilling, else progress would be very slow.

With any machine that takes no time to set up or take down and permits the holes to be put in just as they would by hand, there can be a great saving effected in power and in the number of feet of holes necessary to be drilled, over any of the old style mounted machines.



In order to get the good out of hand machines, the hole should not be put in deep, most of them not more than 48 inches. They should be put in to take advantage of the ground, and should be shot twice a shift or oftener, or, if this is impossible, the drill must have plenty of space to work in, as much as at least two headings or a long stope.

A small streak of ore can be kept just as clean when our machines are used, as if it was broken by hand. All miners will admit that in ordinary ground rock can be broken cheaper by hand than with the old style mounted drill if we leave out the question of time. Now, if this is admitted, the proposition becomes simple, for with a Murphy drill a man can drill with ease four times as much as he can by hand. He can put in the holes to take advantage of the ground the same as in hand work and use no more powder per ton of rock broken, than in hand work.

Now, we have only to figure on the cost of operating the machine. The wear and tear of the machine is very slight. We have had them running for six months without a single thing breaking or wearing out, and on an average they will not cost more than $3.00 per month to keep in repair.

The Murphy drill takes about one-third as much air as the two and one-half so called one-man baby machines.

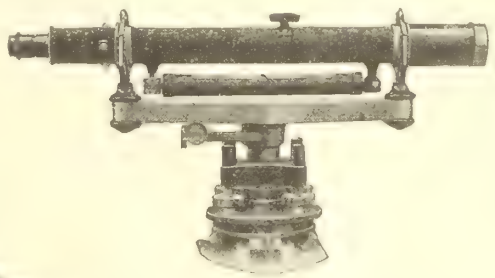
These two items will cost less than one-half the wages of a man, therefore we can break in a day with one man,

using our hand drill, as much as four men could break by hand, with the expense of one and a half times the wage of one man.

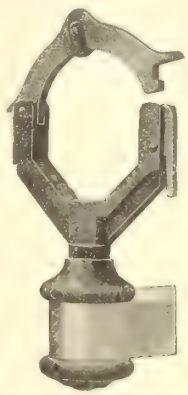
From the foregoing description and cut it will be seen the Murphy air hammer drills are adapted to all kinds of practical mining, such as sinking, stoping, tunneling and block-holing; they are adapted to be used with solid or hollow steel, wet or dry.

A hand drill may be changed to a stoping drill, or a stoping drill to a hand drill, and that either may be changed to a water machine, or may be mounted on a column for tunneling. It is therefore possible to equip a mine with Murphy drills and use no other kind, as one line of repair parts will suffice for all machines. The repair parts for a Murphy drill are made strictly interchangeable and are suitable for all styles of our machines. We are the only manufacturers who can equip a mine with air hammer drills for all kinds of mine work. Some manufacturers can supply a hand drill for drilling dry only and a stoping drill for dry work only that cannot be mounted on column, but these are entirely different machines and require a different line of repair parts. Other manufacturers furnish water machine for tunnel work, but this must always be used on a column or cross bar, and its parts are not interchangeable with either the stoping drills or hand drills. You can readily see the advantage of having a line of drills with parts strictly interchangeable and at the same time a drill that is capable of handling all lines of mine work. The advantage of our system will be manifest to any miner. It is not necessary to carry so many repair parts, as the machines are all alike. When a miner has learned to run and understand one of our machines, he understands them all. When the mechanic understands one, he understands all. That these machines are unequal for speed for drilling, durability and minimum consumption of air for work prformed, will be testified to by the hundreds of miners who have recently adopted them.

The Murphy Drill is provided with what is claimed to be the only practical, automatic, lubricating device ever put on a drill. It is as excellent as it is simple. To reach the cylinder, the oil in the reservoir must pass through a leather gaskit, which is made of heavy sole leather, unperforated. The oil must soak through it. This it does just fast enough to keep the cylinder properly lubricated. This advice is more important than may appear at first sight, for miners are so notoriously careless about oiling their drills, and if a drill is not properly oiled it will not do nearly the work and will wear out earlier.



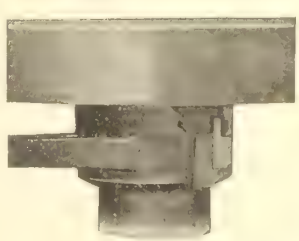
Examination of the cross cut will show the simplicity of the machine there being but one moving part. Every part can be readily removed and replaced if they should become worn as all repairs and parts are made strictly interchangeable. Anyone can understand it, anyone can run it.



A NEW WYE LEVEL.

We show herewith a new Wye Level having several improvements, which has just been placed on the market by Wm. Ainsworth & Sons, the well known instrument makers of Denver, Colorado, U.S.A.

The principal parts of the instrument are made of the hardest bronze alloys to gauges, and, with the exception of the centres, strictly interchangeable. It has an 18 inch 35 power erecting (or inverting) telescope with 1⅜ inch objective, 8 inch 10 seconds level with graduations on glass, 11 inch bar, clamp and tangent, long steel centres of large diameter and four screw leveling head of improved construction.



Especial attention has been given to the construction of the telescope, where owing to improved methods and by working to within limits of .00005 inch it has been possible to construct a telescope that will remain in collimation throughout its entire travel without making use of the objectionable object slide adjustment, which until now has been the only solution of this difficulty.

The Wyes are of light but rigid construction with improved spring latches for locking, that are quickly operated and very solid. The clips carry fibre tipped spring plungers that hold the telescope firmly in the wyes.

The leveling head is of the same construction as that used for their transits but without shifting center; and owing to especially accurate construction cannot be cramped in any position.

The spindle and clamp are protected against the entrance of dust by a light ring threaded onto the spindle which carries on its inner diameter a felt ring that is in constant contact with a projecting ring on the clamp.

The instrument is packed with the usual accessories in a mahogany carrying case, the telescope being removed from the Wyes to prevent damage to the collars when carrying and while in transit.

This instrument and an improved Railroad Wye Level are fully described in bulletin BX-16, which will be sent on request.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay, Oct. 2, 1908.—The pall of smoke which during the latter half of September covered the River St. Lawrence and extended far into the Gulf forbade all navigation for a space of seven or eight days, and caused a great deal of enforced idleness at the mines. The output of the Dominion Coal Company's collieries, for example, would under ordinary circumstances have reached 330,000 tons, but in consequence of the numerous shutdowns that were found necessary, it has amounted to only 260,000 tons.

It has been a striking object lesson on our dependence in Cape Breton on the St. Lawrence market as an outlet for our coal production. At the very least one-half of the saleable output of the Cape Breton collieries is market up the St. Lawrence. It is a peculiar trade. The season is rendered very short by the climatic conditions, so short indeed that it is beyond the capacity of the mines to produce the shipments required during the six or seven months of open navigation. In order, therefore, to equalize production and distribution as much as possible, large banks or stores of coal must be accumulated at the mines during the winter, and equally large stores must be accumulated at the discharging points in order to carry the requirements of the trade over the season of closed navigation. Such a trade requires a large amount of capital, first for transportation, and secondly for wages in order to carry the workmen over the winter and provide the stores of coal required for the summer. This trade is also subject to strenuous American competition, and is altogether beset by so many difficulties and so nicely balanced that very little is needed to render it an unprofitable one. It is, therefore, of the utmost importance to Cape Breton that no legislation be passed that would tend to increase the difficulties of this trade, which has no parallel anywhere, that we are aware of. Any such law as an Eight Hours Act, for instance, might have far-reaching and disastrous consequences that its light-hearted advocates do not foresee.

Mr. Kier Hardie, the leader of the Independent Labor party in England, recently addressed a meeting in Glace Bay, which was held in the interests of the United Mine Workers of America. Mr. Hardie recently achieved notoriety by preaching sedition to the natives of our Indian Empire, and we understand his mission in Canada is to help in the formation of a Labor party in the Federal House similar to that of which he is the leader in England. We hope Mr. Hardie's extensive tours are improving his knowledge of geography, because he needs lessons in that particular science, especially as it applies to the British Empire. It is just about a year ago that Mr. Hardie received a letter from Woolongong, New South Wales, Australia, complaining of the bad state of trade in the coal mining region of New South Wales. Mr. Hardie immediately wrote to leading newspapers in England warning miners not to accept invitations to go to "certain unspecified mines near Sydney, Nova Scotia," and finished his letter by saying that he hoped his warning "would not be in vain." Perhaps it may by this time have penetrated Mr. Hardie's consciousness that Sydney, Nova Scotia, is in Canada, and not in Australia. We never heard that Mr. Hardie acknowledged his error or tried to remove the effects of his letter, although it was promptly contradicted by the Agent-General for Canada in London.

Another gentleman who spoke at this same meeting conveyed some remarkable information to his hearers, from which it appears that we have been living in blissful ignorance of our woeful state. Mr. Sherman, the gentleman in question, and a vice-president of the U. M. W. A., told his audience that they compared very unfavorably with the miners of the West, and that their faces showed that they worked in "ill-ventilated mines." Anyone who knows the Cape Breton miner will smile at this statement, and take it just for what is is worth. When one speaks of the native miner of Cape Breton it must be remembered that he comes of an ancestry of miners, and that he is one of a very distinct race. Out in the West they have no indigenous race like the Highlander of Cape Breton. The miners of the West are gathered from all parts of the world, and it is more than possible that the fine specimens Mr. Sherman has seen there were born down here. It is rather more than likely. But it would be a work of superfluity to attempt to prove the superiority of the Cape Breton miner's physique. Everybody knows it. As to the ventilation of our mines, we think Mr. Sherman is as far astray as he is on the other matter.

The mines of Cape Breton need fear no comparison with any mines on this continent, or for that matter on any other continent. Our mines are well ventilated, well laid out, superbly equipped, and safety is a prime consideration in their management. Mr. Sherman can bring ordinary mortality statistics, ordinary and fatal accident rates, ventilation figures and anything he likes from the West, and we will go one better in Cape Breton, every time. We would remind Mr. Sherman that it is always well to speak a modicum of the truth, and to suppose some spark of intelligence in the audience, even in the benighted East.

ONTARIO.

Cobalt.—The Kerr Lake Mining Company.—The Annual Report of the Kerr Lake Mining Company for the year ending August 31st has been issued. Great credit is due to the management of this company for the complete information furnished and the general excellence of the report.

During the fiscal year a total of 1,473,712 ounces of silver were produced at an estimated value of $787,554. The cost of producing this ore, including all development costs in the mine, shows a total of $139,530.97, leaving a gross profit of $643,023.76. The average value per ton is over $1,500.

Accompanying this report are maps showing the underground development and the surface plants, etc. On vein No. 7 a shaft 180 feet deep has been sunk. On vein No. 3 a depth of 325 feet has been reached. Considerably over a mile of underground work has been done. Five veins on this property have already been located in which ore has been blocked out. Vein No. 3 has produced 168 tons, and vein No. 7 363 tons. Less than 25 per cent. of the property has been developed, but from the valuable veins uncovered in the development work so far done there is every reason to believe that other veins of equal richness will be encountered with further development work. The showing of the property for the yast year is a remarkable one.

The following is the statement of the Secretary Treasurer of the assets and liabilities:—

"To the Shareholders and Directors of the Kerr Lake Mining Company:

"I herewith submit my report of the Assets and Liabilities, together with Profit and Loss account, for the fiscal year ending August 31st, 1908.

"It is most gratifying to be able to report to you that I received the sum of $740,435.80 from the sale of ore during the year. There is still outstanding and due to us by the smelters $116,772.76, making a total of $857,208.56.

"The entire plant, including machinery and buildings, has been charged off to Profit and Loss.

"In previous years amounts received from the sale of ore have been as follows:—

In 1906	$176,717 00
In 1907	347,855 38
In 1908	857,208 56

showing a steady increase.

"Dividends paid were as follows:—

In 1906	$190,000 00
In 1907	210,000 00
In 1908	360,000 00

"The whole is respectfully submitted.

"By order of the Board,

"JACOB A. JACOBS,

"Secretary-Treasurer.

"New York, City, N.Y., Sept. 23rd, 1908."

La Rose.—The net earnings of the La Rose Mine for September were $101,000, as compared to $108,000 for August, $127,329 for July, and $82,807.55 for June.

Kerr Lake Miners Winning Drill Contest, Labor Day.

City of Cobalt.—The City of Cobalt Mine is rapidly coming to the front as a producer of high-grade ore. In the week ending October 2nd 191,600 pounds of ore was shipped, placing the City of Cobalt fifth in the list of shipping mines. Up to and including October 1st practically 500,000 ounces of silver have been taken out of the property, netting approximately $250,000. On July 3rd a dividend of 3 per cent. with a bonus of 2 per cent. was distributed. On October 15th a dividend of 3 per cent. with a 2 per cent. bonus will be distributed. It is estimated that the ore in sight guarantees a quarterly dividend of 5 per cent. for four years. A new plant is being installed, consisting of a 12-drill Sullivan compressor, enlarged boiler capacity, etc. The main shaft is down 137 feet. Approximately 1,000 feet of drilling has been done at the 65-foot level. Three hundred and fifty-six feet of drifting and cross-cutting has been done at the 137-foot level. In a cross-cut from the lower level a vein known as No. 2 was encountered, and a winze sunk on this vein 60 feet, and at 200 feet a new vein was struck, which is about six inches wide and carries very high values of native silver.

Silver Cross.—Mr. Lewis Jennings, who controls the Silver Cross Mine, has just completed arrangements to resume work on the property. The No. 1 shaft was sunk to 100 feet, and No. 2 shaft to 46 feet when work was discontinued. The No. 2 shaft is on a very wide true vein of calcite and cobalt. This vein will be cut at the depth of 200 feet with a diamond drill. A force of men will be put to work at once trenching, and a diamond drill started. The property is well located, and the formation is very favorable.

Cochrane Cobalt.—Arrangements have been made for the sale of sufficient treasury stock of the Cochrane Cobalt Company to provide funds for thorough development of the property. This should add a new shipper to the S. E. Coleman district, as the indications are exceedingly favorable, and the property is undoubtedly a valuable one. Mr. Floyd Harmon, who developed the Temiskaming Mine, will have charge of the Cochrane. Mr. Harmon has had a very extended experience in the Cobalt field, and under his management the property will be developed to the best advantage.

The Beaver Mine.—At the 200-foot level from the main shaft a drift is being driven in to cut a number of veins which were located at the 75-foot level. Seven veins in all have been cut at this level, and all of these showed every indication of values at depth. The experience of Temiskaming and Shamrock, which adjoin the Beaver on the south and north, has shown that the silver values are not located at or near the surface. Developments at 200 feet should prove up some important vlaues.

The Silver Cliff.—The Silver Cliff Mine, which is operated by a syndicate of Toronto capitalists, is rapidly taking its place as one of the important shipping mines of the camp. Since the present management took possession on July 1st over $125,000 worth of ore has been taken out. Several new veins have been opened up, and the No. 1 vein proved to carry high-grade ore from the surface to the 170-foot level. The main workings of the mine are from a drift into the face of a high bluff, making mining very inexpensive.

Temiskaming and Hudson Bay Company.—At the annual meeting of the shareholders of the Temiskaming and Hudson Bay Company the directors were authorized to issue 23,238 additional shares of stock at the par value of $1 per share to stockholders, at a ratio of two shares for each one share held. The capital stock issued is 7,246 shares of the 25,000 shares of authorized stock. The shares are quoted in the market around $220 each.

It is understood that the new issue is made at the request of brokers, in order to facilitate trading in the stock.

The President reported that the patent to the lot in dispute would be issued by the Government on agreement of the company to pay a royalty of 15 per cent. of net proceeds received from the smelters.

The Red Rock Mine.—The Red Rock Mining Company has gone into liquidation, owing to a debt of $10,000. The directors of the company are as follows: F. P. Chapin, President; A. E. Dyment, Vice-President; R. M. Green, Secretary-Treasurer; R. R. Gamey, A. E. Osler, and N. S. Thompson.

The capitalization of the company is $1,000,000; the stock was all issued. At one period there was every indication that the territory around the Red Rock and Green-Meehan would prove to be very valuable, but the history of both these properties has been unfortunate.

The Otisse Claim.—The Otisse property at Silver Lake, in the Montreal River district, has just been sold to a Toronto syndicate organized by Mr. E. D. Warren. This property has undoubtedly the best surface showing of any of the claims in the Montreal River district, and the development of it under proper

management will do more to promote the interests of the district than anything so far in the history of the outlying camp. A large sum of money was paid out for the property after reports by first-class engineers, and sufficient capital has been provided to thoroughly develop the property. Mr. Frank C. Loring, who has been for some years prominent in the Cobalt District, is to have general supervision of the development work. Mr. Loring is interested also in the promotion. Although no sinking has been done and practically no trenching, twenty-two veins have been located on the property, six of which show native silver. If development with depth shows a persistence in the silver content, the Otisse property will undoubtedly be an important factor in the silver production of the district.

BRITISH COLUMBIA.

Rossland.

The Rossland mines are working along more steadily than the mines of any of the surrounding districts. During the whole of this year they have maintained their regular shipments from week to week, making no runs to high record marks nor falling below their general average. The Boundary mines have been affected by difficulties arising from lack of coke, money and cars, but none of these conditions have affected the Rossland mines to a noticeable extent this year.

The Centre Star, Le Roi, Josie, Giant-California, St. Elmo and Evening Star have appeared on the active shipping list during the past two weeks, and the situation throughout the camp generally is one of persevering activity.

While much might be said of the every-day work at the Centre Star and Le Roi mines, nothing out of the ordinary has occurred. Ore is being opened up in a satisfactory way and the usual development and mining operations have been carried on. On the Surprise property of the Le Roi 2, Ltd., a tunnel has been started towards the ledge. At the Giant-California, having failed to cut the sought for ore body with the long cross-cut, the operators are now doing considerable diamond drill development, by means of which it is hoped to locate the continuation of the lode known to exist in the Annie claim of the Le Roi Two, adjoining, which ore has been followed up to the side lines of the California. The location of ore in the Giant-California means much to Rossland camp in an economical way, and it is hoped that this concern will be repaid in a rich manner for the great amount of developement work they have done on the Giant-California during the past eighteen months.

At the Le Roi mine during the month of August they expended $9,000 on development work, in the course of which a good body of ore was encountered on the 1,650-ft. level. The quantity of ore shipped to the Northport smelter was 6,191 tons, which carried 2,837 ounces of gold, 3,350 oz. silver, and 147,000 lbs. copper. The estimated value of the gross output is $77,000, and the profits $15,000 for the month. The Le Roi has been making good progress during all of the present calendar year, and a good report from the directors for the past fiscal year should be the result.

It is reported that they have exposed a five-foot ledge of good-looking ore on the Inland Empire. No assays are yet to hand.

From time to time the Consolidated Co. has been disposing of the machinery contained in the huge structure erected several years ago for the reduction of Rossland pyritic ore, and which is situated at Trail, B.C. Most of this machinery has been shipped to the various mines of the Consolidated Co., where it has been put to use advantageously. Most of the concentrating machinery proper has been shipped to the St. Eugene concentrator, and the concentrator at Trail is fast being dismantled. The Rossland Power Co., the organization that launched this enterprise, after several months of apparently successful experimental work at Rossland, met with a heavy loss and much disappointment when it was found that the idea was not practicable. The concentrator was too far from the mines, and freight rates, loss in the tailings and general recalcitrant character of Rossland ore led to its failure. The capitalization of the Rossland Power Co. was originally $600,000; when it was absorbed by the Consolidated the assets of this company were taken in at $60,000, and even at that it is safe to say the Consolidated Co. will incur some loss after the transaction is cleared up.

There has been a lot of work done towards the concentration of Rossland low-grade ore. A cyanide works on Sheep Creek, below the camp, started off to revolutionize mining in this section some years ago, but was a dismal failure. The Le Roi Co. has an experimental concentrator on the Black Bear claim consisting of crushers, Chilian mills, settlers, Wilfley tables, etc., which is standing idle at present.

The White Bear stamp mill, Wilfley tables and oil plant are idle, but it is said that this concern made a small profit on their concentrating, while working. Several inventors have brought in their tables for catching the gold and other values in tailings, have been seen working at the foot of the ore dumps for a time and have eventually boxed up their tables and moved to other fields. The Le Roi Two, Ltd., have been working their concentrator steadily for the past couple of years. During the month of August they shipped 69 tons of concentrates, which netted them $950, or $13.76 per ton. This figure, after deducting cost of mining and treatment in the concentrator, leaves them a good profit. It may be said, however, that the "second-class ore" of the Le Roi Two is of a higher grade than that of either the Le Roi or Centre Star mines.

Boundary.

Having survived the coke shortage in good form, and having run the weekly shipments once more up to the high tonnage mark, the big producers of this district are now threatened with a setback in the shape of a car shortage, there being a lack of cars to haul fuel, owing to the demand for cars to take the big wheat crop of the North-West to the Eastern shipping points. The shipments from the district for the week ending Oct. 3 were but 34,959 tons, as compared with the week ending September 19, which totalled 41,230 tons. The Granby, Snowshoe, Mother Lode and Oro Denoro were the only shippers during the week ending October 3.

The mines of the Dominion Copper Co. have been shut down for the present, only a pumping crew being retained at the mines. The company has drifted into such a position, in consequence of the very low price of copper, that it is believed that nothing short of reorganization will place it where they will be able to make their mining and smelting operations pay; that is, considerable capital is required to get the enterprise into good working form, and it is likely that a receiver will be appointed and the company reorganized. The mines of this concern never looked better, and they were working along in good shape until the coke shortage, which followed the Fernie fire, gave them just enough of a setback to precipitate matters. In order to finance the 10 per cent. sinking fund requirements of the $800,000 outstanding bonds, in June last, it is stated that many of the large bondholders took notes for their interest, and now that other heavy payments are about due it is felt that the most expedient thing to do is to get the business organized on a good basis before doing any more work. It is safe to say that when this reorganization has taken place and the company has sufficient funds to make a good start, and equip the mines and smelter with up-to-date ore handling machinery in every respect, then this company will be able to forge ahead to the ranks of profit payers, for their mines are certainly as good

as other Boundary properties that are being made to pay and, in some respects, the ore found in them carries higher values.

The big find of chalcopyrite in the Emma mine of the B. C. Copper Co. has done much to stimulate development in the Greenwood district, and has, to some extent, been an aid to the formation of a company to develop the valuable Greyhound group of mines that adjoin the property of the B. C. Copper Co. The B. C. Copper Co. is now working, in addition to the Mother Lode and Oro Denoro mines, and the properties recently acquired in Wellington camp, the Napoleon and Acme mines, and other properties in the State of Washington just across the Boundary line. At the Napoleon they are extracting 200 tons of ore per day that will average $13.35 per ton. This output can, and will, be considerably augmented when copper advances. The Athelstan Fraction and Molly Pritchard claims which the B. C. Copper Co. recently bonded for a figure around $100,000, will prove valuable to them, inasmuch as the ore is useful as a flux, and in addition carries paying quantities of gold and silver.

A car of ore has been sent by the Consolidated Co. from the War Eagle, Phoenix, to the Trail smelter. The Granby Co., after much experimenting, are now fitting their powder thaw house with an apparatus whereby air-warmed by electric coils will be driven into the thawing room, and they will do away with the steam. It is thought that the air will thaw the powder in a more uniform away and will be less liable to cause accidents than any other form of heat.

Nelson.

The Silver King mine at Nelson has resumed ore shipments, the product now being treated at the Trail smelter. A series of test runs have been made at the Granite-Poorman mine by the lessees. The highest returns were $2,300 for the nine-day run; other runs netted $1,200 and $1,100. The gold obtained from Granite ore is quite coarse, and is mostly caught in the batteries. Twenty tons of concentrates were also obtained in addition to the gold for the three test runs. Experts have been examining the May and Jennie claims of the Reliance Mining Company for American capitalists. The Fisher Maiden mine has made a shipment of 22 tons of sacked ore to the Trail smelter.

A body of $100 ore has been opened up on the Second Relief mine, Salmo district. This ore will not be put through the mill, but is rich enough to ship direct to the smelter. Fifteen men are at work on the Yankee Girl property. The Arlington is shipping 100 tons of $75 ore per month. The control of this company is largely held by English capital.

A body of good shipping ore has been encountered in the workings of the Aurora, across the lake from the St. Eugene. The concentrating ore found in the lower tunnel carries 11 oz. silver and 24 per cent. lead. The operators are confident that they will find a continuation of the St. Eugene lead, and development work is being continued. Several carloads of ore on the Society Girl will be shipped over snow roads to the reduction works this winter. A new boiler-house is being erected at the St. Eugene. The mine is working and shipping steadily, and is looking good all through.

GENERAL MINING NEWS.

NOVA SCOTIA.

North Sydney.—A continuation of the Collins coal seam has been discovered underlying the seam operated by the Mackay Mining Company.

Halifax.—On the property of the McCallum syndicate fourteen veins of scheelite have been cut. Production on a small scale will soon be commenced.

West Gore.—It is rumored that the legal difficulties in which the Dominion Antimony Company was involved are now cleared away, and that work is to be resumed.

ONTARIO.

Cobalt.—Several properties have been added recently to the list of those being worked under lease. Among these are some of the Davis Silver Cobalt Mines Company's claims. The custom of working on lease is widespread in metalliferous districts in the United States.

Bancroft.—The sodalite property near this place has changed hands. Mr. T. Ludyard, the former owner, has sold it to an English syndicate. It will be operated continuously.

BRITISH COLUMBIA.

Ashcroft, Sept. 26.—Mr. J. C. Gwillim, Professor of Mining at the School of Mining, Kingston, Ontario, has spent part of this summer inspecting the Telkwa, Bulkley and Babine districts of Northern British Columbia, on behalf of the Consolidated Mining and Smelting Company.

"Concerning mineral resources," writes Mr. Gwillim, "ores of lead, silver and copper have been found over a very large territory, but little has been done in the way of development. The distances are great, and at present the transportation is all by pack animals. A wagon road is being built from Hazelton to Aldermore, a point sixty miles south from this trails of twenty and thirty miles branch off into the mountains on either side. The country is a favorable one to prospect, but development and cheap transportation must come about before there will be any production of large tonnage.

"Anyone entering the district at this stage should receive easy terms and plenty of time to develop mineral properties, because the cost of development will be great, and also experimental, and the time of realizing from ore production cannot come until the Grand Trunk Pacific is on a shipping basis.

"The Telkwa Mines, the Telkwa Mining, Milling and Development Company, and James Cronin, deserve much credit in opening up the properties which they have under such disadvantages in the matter of long pack trails and insufficient skilled mine labor and equipment.

"Rumors and reports from Ingenika and McConnell Creek are not optimistic."

Nelson.—The Kootenay exhibit of ores at the Spokane Fair is expected to win the cup offered for the best exhibit. Messrs. T. G. Proctor and A. H. Gracey have been active in the movement. Mr. T. Brown is in charge of the exhibit.

Nelson, Oct. 3.—The shut-down of the Boundary smelters in the earlier months of the year has not affected the ore outputs of Boundary and Kootenay to as large an extent as was expected. The total output to date is 1,332,854, as compared with

1,364,271. Both the Boundary and Rossland districts show increases—70,061 and 5,937 tons respectively. The falling off of Slocan outputs is the present drawback.

Nelson.—On September 21st a delegation, consisting of Messrs. R. Irving, F. T. Snyder, L. Pratt, and J. Whittier, representing the Canada Zinc Company, waited upon the City Council of Nelson for the purpose of requesting that the refusal of the city to turn on their electric power over the company's lines be reconsidered. The decision has been left to Engineer Cecil B. Smith.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

Messrs. Bolckow, Vaughan & Co. have acquired the Belmont iron ore mines near Guisborough-in-Cleveland, and will shortly reopen them.

The annual report of the Labor Department of the Board of Trade shows an increase of miners' wages during 1907 in every coal field, ranging from 15 per cent. in Lancashire, Yorkshire and the Midlands, to 43¾ per cent. in Scotland. The total number of workpeople affected was 806,339, and the net amount of increase in weekly wages was £173,613.

The question of the afforestation of mountain lands in South Wales is being prominently discussed in its relations to the mining industry. It is urged that the unemployed could be furnished work in planting spruce and fir trees near the collieries to furnish a home growth of pitwood, which would compete with the foreign-grown wood now imported, and keep down prices.

BELGIUM.

Out of 42 blast furnaces in Belgium, only 30 are in operation. The output of pig iron for the first eight months of the year was 782,700 tons, as compared with 950,640 tons for the corresponding period of 1907.

RUSSIA.

Coal has been discovered near Tschernowskoje, on the Transbaikal Railway, the deposit being estimated at not less than 600,000,000 poods. A syndicate is being formed to take over all the collieries in the district.

A geological survey undertaken this year in the Simbursk government has disclosed rich deposits of bituminous schist, a large quantity of which is fit for fuel, also sulphur and phosphorites, including a considerable quantity of phosphoric acid.

AUSTRIA.

Two Heroult electric furnaces for steel manufacture, one of 2½ and the other 3 tonnes, were recently installed at the works of Messrs. Bohler, at Kapfenburg, Styria.

AUSTRALASIA.

At the South Blocks, Broken Hill, New South Wales, the cost of copper production has been reduced to a minimum of 15s 0¾d per ton.

The Victoria Minister of Mines, in a recent speech, stated that the latest information from the State geological surveys showed that there were 350 miles of auriferous reefs in Victoria, of which it was estimated that 250 miles were not payable at present, although they might be some time.

The Anchor Company, which has spent £100,000 in tin mining operations in Tasmania without being able to pay dividends, is asking a loan of £5,000 from the State Government.

The main shaft in the North Lyell copper mine, Tasmania, is down 90 feet below the 1,000-foot level, and the next level will be run at 1,100 or 1,150 feet.

The State coal mines of New Zealand during the year ending June 30th shipped 237,309 tons of coal, valued at £109,259, of which 115,172 tons were supplied to the Railway Department and the remainder to shipping companies and private consumers.

JAPAN.

In the Province of Satsuma there are now nearly 200 gold mines, the annual output of which is estimated at three million yen. One of the most important is owned by Prince Shimazu, and embraces 2,360 acres, worked by modern methods.

UNITED STATES.

A deal is reported between the Hubbard-Elliott Mining Company, owning extensive copper properties in Alaska, and L. Hirsch & Co., of London, England, involving the formation of a new corporation capitalized at $30,500,000.

A $1,500,000 concentrating plant is to be erected by the Oliver Iron Mining Company on their property at the west end of the Mesabi range.

Advance figures published by the United States Geological Survey give the gold production of California for 1907 at $16,727,928, a decrease of $2,004,525. Silver was produced in the State to the value of $751,646, a decrease of $66,182.

The Westmoreland Coal Company, of Pennsylvania, has completed plans and appropriated $1,000,000 for the development of a tract of 20,000,000 acres in Westmoreland County. Two mines are to be opened and a new mining town founded, which will be named "Yukon."

The H. C. Frick Company is about to erect three new coke plants in the Connellsville district, Pennsylvania, at a cost of about $4,000,000.

SOUTH AFRICA.

Owing to an increase in the demand for diamonds in the United States and Britain, the De Beers mines, which had been working short time, have resumed full operations.

The Natal Government will appoint a commission to enquire into the best means of developing the mining industry and to revise the mining laws.

MEXICO.

Coal has been discovered on the Laguna de Palos Blancos land in the Mocorita district of Sinaloa. It is reported that there are indications of a large deposit of good commercial quality.

A contract has been made by Manuel Cuesta Gallardo, of Guadalajara, with Siemens-Schuckertwerke, of Berlin, Germany, for electrical machinery worth over $7,500,000 for power and irrigation enterprises, including the supplying of electric energy to the Amparo Mining Company in the Etgatlan district.

COMPANY NOTES.

AUGUST REPORT OF LE ROI.

Shipped from mine to Northport during the past month, 6,191 tons of ore, containing 2,837 ounces of gold, 3,350 ounces of silver, and 147,000 pounds of copper. The expenditure on development work during the month was $9,000. Have discovered a good body of ore at the bottom of the mine, 1,650-foot level, south vein; grade of ore varies, but is considerably above the average value of other parts of the mine. According to the above, the gross value of the output was $77,000, which value means that a profit of about $15,000 had been made for the month of August.

FINANCIAL STATEMENT OF THE CONSOLIDATED MINING AND SMELTING COMPANY OF CANADA, LIMITED, FOR YEAR ENDING JUNE, 30TH, 1908.

LIABILITIES.

(*Continued from last issue.*)

FINANCIAL STATEMENT.

After writing off $132,843.20 depreciation upon plant and equipment (as compared to $91,705.50 depreciation marked off during the previous year), $27,127.55 on account of depreciation of stores and doubtful accounts, and charging to profit and loss account $564,226.06 expended upon development, the operating profit shown is $43,415.93. Having provided for the above, and the payment of dividend No. 7, amounting to $66,940.00, the balance at the cherdit of Profit and Loss Account is $32,061.93.

As mentioned in the Annual Report of the previous year, due to circumstances beyond the control of the Company, the stock of ores and metals on hand June 30th, 1907, was very large. Before it was possible to market these metals, their values commenced declining rapidly. The fall in prices during the year is shown by the following quotations:—

	London. Lead.	New York. Silver.	New York. Copper.
June 30th, 1907.....	£20 0 0	67¼ Cents	22⅛ Cents
June 30th, 1908.....	12 5 0	53⅝ Cents	12½ Cents
Difference	£7 15 0	13⅝ Cents	9⅝ Cents

Had it been possible to market the metals on hand June 30th, 1907, at quotations of that date, and to market the metals contained in the ores received during the year at the same quotations as those allowed the mines, then the Consolidated Company's profits would have been increased by over $430,000.

During the year additions to the various plants have amounted to $315,562.22, and the cost of new properties and their development to $621,894.73, or a total of $937,456.95. This amount has been provided by the payment of $416,056.95 cash from working capital. The balance of $521,400 is represented by capital stock issued in payment for new properties.

The Snowshoe overdraft guaranteed by the Consolidated Company has been reduced from $46,196.07 to $29,707.92.

The advance to the Canadian Metal Company of $125,000 (secured by a first mortgage upon the Bluebell Mine and Concentrator, and Frank Zinc Smelter), will be repaid October 31st, 1908. A portion of the above advance was used in the construction of a concentrator at the Bluebille Mine, which is now in operation. The product is being regularly shipped to Trail for treatment.

DEVELOPMENT.

There are 19 miles of underground development or narrow work in the Centre Star Group, 12½ mlies in the St. Eugene, and 3,300 feet in the Richmond Eureka. The Consolidated Company has done 1,366 feet of narrow work and 1,348 feet of diamond drilling on the Snowshoe Mine. The Phoenix Amalgamated has a total of 800 feet of narrow work, a number of open cuts, and 1,749 feet of diamond drilling.

Following is the development or narrow work (given in feet) which has been driven during the year:—

	Drifting.	Cross Cutting.	Raising.	Sinking.	Total.	Diamond Drilling.
Centre Star and Idaho	7.218.0	3,152.0	481.5	518.5	11,370	10,032.9
War Eagle and Iron Mask....	2,568.5	661.0	418.5	100.5	3,748.5	4,160.1
St. Eugene	7,934	1,843	2,596	266	12,639	4,569
Richmond Eureka	1,125	266.0	313	0	1,704	0
Snowshoe	358	205.5	351.5	0	915	1,126
Phoenix Amalgamated .	0	246	75.0	30	351	1,749

The ore reserves in the Centre Star Group, Rossland, have been increased. Shipments from these properties for the year have been 175,799 tons, containing a gross assay-value of $1,915,953.79 as compared to 81,788 tons containing a gross assay-value of $893,249 during the previous year.

The lower workings of the War Eagle and Iron Mask Mines have been producing high-grade ore during the year. For example, during the month of June, 2,133 tons were shipped, containing a total gross value of $50,700, or nearly $24.00 per ton. The occurrence and development of this higher grade product in depth are encouraging features of the year's operations.

The 12th level Centre Star has yielded a large tonnage. The 13th and 14th levels have only, as yet, added slightly to the ore resrves, but prospecting is still incomplete upon these levels.

The Centre Star Shaft is now 20 feet below the 16th level, which makes a total vertical depth below the collar of the shaft of 2,050 feet, and measured along the slope 2,183 feet. Within another month sinking will be stopped and the prospecting and developing of the 15 and 16 foot levels commenced.

Large bodies of heavy sulphide ore have been found in the Idaho, but the gold contents have been disappointing.

The probable ore reserves of the St. Eugene Group, Moyie, are nearly 50 per cent. greater than a year ago. Ore 50 per cent. better in grade than last year's average has been found between the 1,900 foot and 2,000 foot levels. Between the 1,700 foot and 1,800 foot levels a new avenue, called No. 2½, has been located, and this avenue has also been found and partly developed upon the 1,900 foot level. Another new avenue (which will be designated as Fifth Avenue) located approximately 120 feet farther in the hill than Fourth Avenue, is being developed on the 1,900 foot and 2,000 foot levels.

In the report of last year it was mentioned that the 2,000 foot level did not promise to yield as much tonnage as the 1,900 foot level, but present indications are that the 2,000 foot level will produce more than the 1,900 foot level, or any other level in the mine. The grade of the ore is, however, lower than that produced from the upper workings. Some bodies of low-grade matrial have been found on the 2,100 foot level, and a raise from this level shows ore of workable grade. Prospecting upon this level is still incomplete. Drifting and cross-cutting upon the 2,200 foot level are progressing, and one or two low-grade ore bodies have been found. It will require six months or a year to determine the amount of ore upon this level.

The main St. Eugene shaft is 24 feet below the 2,400 foot level or 749 feet vertically below the collar of the shaft.

The Richmond Eureka, at Sandon, is developing very satisfactorily. An aerial tramway was completed last January, and regular monthly shipments of 250 tons of ore are being made,

containing approximately lead 18.5 per cent, silver 55 ounces per ton. The probable stoping area is seven or eight times greater than was estimated a year ago.

Prospecting upon the Phoenix Amalgamated Group was started last summer, but was discontinued at the time the Snowshoe Mine was closed. It was decided to postpone further prospecting until the latter resumed operations. A large amount of low-grade ore, containing a sufficient excess of iron to make it profitable to mine. The extent and commercial value of this body is not yet known.

The tonnage developed in the Snowshoe Mine (leased by the Consolidated Company) is the same as last year. No ore has been found below the faults which cut off the ore bodies in depth, but the chances are favorable for finding additional ore bodies near the surface.

The Snowshoe Mine was shipping 25,000 tons per month when the general demoralization of the copper market occurred. For this reason the mine was closed in November, 1907. The prices for copper having improved, and the general situation being better, it has been decided to commence shipments within the next few weeks. The average assay of 135,500 tons shipped by the Consolidated Company has been: Gold, 0.59 oz.; silver, 0.32 oz.; copper, 1.3 per cent.

CONSTRUCTION AND IMPROVEMENTS.

The amount expended upon new construction and improvements during the year amounted to $315,562.22. A portion of this amount was used in completing work started during the previous year, and most of the remainder upon the following:—

Equipment of the Richmond Eureka Mine, including an aerial tramway; buildings and equipment at the Phoenix Amalgamated; sorting plant and extensions to the St. Eugene Mill for increasing its capacity and efficiency; additional Huntington and Heberlein Plant at Trail; new anode plant at Trail; electric locomotives, and other electric installations.

RESULTS AND MANAGEMENT.

While the financial results have not been satisfactory, the operating profits having been absorbed by the heavy losses experienced in handling metals on a rapidly declining market, yet from an operating and metallurgical standpoint, the year was a decided improvement upon the one preceding; that is, the tonnage handled was much greater, the values (excepting in the St Eugene) higher, and the recovery of metals and costs at the Trail Smelter and regnery better. Eliminating losses in quotations, the operating profits were larger.

These satisfactory operating resuls are due to the excellent work of the many employees at the various properties, and to the following gentlemen:—

R. H. Stewart, Manager of the Company's Mines; Jules Labarhe, Manager of the Trail Smelter and Refinery; T. W. Bingay, Comptroller; William Chambers, Superintendent of the Smelter; John F. Miller, Superintendent of the Refinery; A. J. McNab and James Buchanan, Metallurgists; R. Purcell, Superintendent of Rossland Mines; S. G. Blaylock, Superintendent of St. Eugene Mines; Charles Biesel, Superintendent of Phoenix Mines; A. W. Davis, Superintendent of Richmond Eureka, and John M. Turnbull, Mining Engineer.

Respectfully submitted,

W. H. ALDRIDGE,
Managing Director.

NOVA SCOTIA STEEL AND COAL CO., LTD.

A dividend of two per cent. on the preferred shares of this company, for the quarter ending September 30th, 1908, has been declared payable on October 15, 1908, to shareholders of record of September 30, 1908.

The transfer books will be closed from the 1st to the 5th of October, both days inclusive.

Granby, for the year ending June 30th, shows a deficit of $320,576, compared with a surplus of $228,019 in 1907, and a surplus of $1,013,617 in 1906. The comparative statement follows:—

	1908.	1907.
Copper, lbs.	21,126,926	16,410,576
Silver, oz.	300,593	257,378
Gold, oz.	40,139	35,083
Gross earnings	$3,790,184	$4,521,548
Charges, etc.	3,435,760	2,673,529
Net profit	$354,424	$1,848,014
Dividends	675,000	1,620,000
Deficit	$320,576	*$228,019
Previous surplus	2,775,757	2,547,738
Profit and Loss surplus	$2,455,181	$2,775,757

*Surplus.

Crediting surplus after charges, etc., $354,424 with the $228,999 charged out for depreciation, the amount earned on the stock for the year would be $583,423, or 4.32 per cent. on the $13,500,000 oustanding.

The price realized on fine copper per pound averaged 13 1-3 cents, and gold $20 per ounce.

The net cost per pound of copper, after deducting values of gold and silver, was 10.31 cents, the cost per ton of ore, including all expenses, was $3.486.

The enormous decline in the price of copper and the marked influence on the cost by reason of the difficulties with which the smelter had to contend, permitted the declaring of only two dividends, viz., one of 3 per cent. on September 30, 1907, and one of 2 per cent. on June 30, 1908.

The Kerr Lake Mining Company's output for the year was 1,473,712 ounces of silver with a gross value of $787,554. To date the company has produced silver to the value of $1,310,000.

The next 5 per cent. dividend on Silver Queen will be paid on November 15. This is the regular quarterly 3 per cent., plus a 2 per cent. bonus, which is now becoming regular.

We reprint here a statement issued by the Crown Reserve Mining Company:—

1. That we have since made another 30-ton shipment, which will net us at least $50,000.

2. That our ore on hand has increased to at least $150,000, a letter from the superintendent received this morning stating that the ore-house is literally blocked up with it.

3. That we will ship two cars of high-grade ore monthly after this month.

4. That all our buildings will be fully completed by the 1st of October next, and that the only accounts now unpaid are current monthly ones for this month.

5. This company is in no way interested in any law suit or litigation of any sort, our property being purchased direct from the Government of the Porvince of Ontario, and title guaranteed by special act of the Ontario Legislature.

6. Our property is easy of access to any shareholder, and is always open for their inspection. We have worked our property from the first day on a strictly business basis, ask no favors of anyone except to be allowed to mind our own business, and to be allowed the privilege of working our own property in the best interests of our shareholders.

JOHN CARSON, President.

Statement of Assets and Liabilities at August 31st, 1908.

Assets.

Audited and verified,

P. S. ROSS & SONS,
Chartered Accountants.

Montreal, Sept. 8, 1908.

Dominion Coal Company, Ltd.

A quarterly dividend of one per cent. has been declared on the common stock of Dominion Coal Company, Limited, payable October 1st, 1908, to shareholders of record at the closing of the books on September 18th, 1908.

Transfer books of the common stock will be closed from September 18th, at 3 p.m., until October 1st, at 10 a.m.

STATISTICS AND RETURNS.

The output of the Crow's Nest Pass Coal Company's collieries for the week ending October 2nd was 9,286 tons, a daily average of 3,214 tons. For the week last year the output was 20,692 tons, a daily average of 3,448 tons.

The output of the Crow's Nest Collieries for the week ending October 9th was 17,463 tons, or a daily average of 2,910 tons.

DOMINION STEEL OUTPUT.

Dominion Steel's output for the month of September was below the August level. The figures:—

Pig iron	18,000
Ingots	16,000
Blooms	17,900
Rails	12,000
Rods	3,200

Shipments of ore and concentrates from the Cobalt camp in the month of September broke all records, totalling 3,120 tons. Shipments in the nine months of 1908 are nearly double those of the same period last year, totalling 16,337 tons against 9,766 in the first nine months of 1907. Shipments by months (in tons) were:—

	1907.	1908.	Inc.
January	980	1,325	345
February	903	1,173	270
March	1,027	1,832	805
April	533	1,317	784
May	1,158	1,601	443
June	1,939	1,581	*357
July	1,327	2,022	695
August	1,139	2,366	1,227
September	760	3,120	2,360
Totals	9,766	16,337	6,571

*Decrease.

NOVA SCOTIA STEEL FOR PAST EIGHT MONTHS.

The coal shipments of the Nova Scotia Steel and Coal Company for the eight months show an increase of 19,767 tons.

August, 1908	64,406
August, 1907	81,590
Decrease, 1908	17,184
August, 1907	81,590
Eight months, 1908	424,644
Eight months, 1907	404,877
Increase, 1908	19,767

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt, and those from January 1st to date:—

	Week end. Sept. 26. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	62,000	912,950
*Cobalt Central	60,000	102,975
Drummond	60,000	1,697,790
La Rose	146,410	6,117,252
McKinley	52,530	2,258,570
Nipissing	231,590	4,363,597
O'Brien	122,480	5,144,687
Right of Way	61,660	1,033,780
Silver Queen	249,000	1,372,990
Temiskaming	60,000	808,620
Temiskaming & Hudson Bay	60,000	1,220,500

*Concentrates.

The total shipments for the week were 1,155,670 pounds, or 578 tons. Total shipments from January 1st to date are 33,130,483 pounds, or 16,565 tons.

Following are the weekly shipments from Cobalt, and those from January 1st to date:—

	Week end. Oct. 3. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	.....	912,950
**Coniagas	63,400	969,360
Cobalt Lake	.....	341,683
Crown Reserve	.....	242,000
*Cobalt Central	.....	402,975
Chambers-Ferland	61,800	183,450
City of Cobalt	191,600	1,197,220
Drummond	60,000	1,065,620
Foster	.....	297,300
Kerr Lake	.....	756,174

Right of Way	.....	1,033,780
Provincial	.....	143,210
Silver Leaf	.....	258,030
Silver Cliff	.....	52,000
Silver Queen	63,000	1,435,990
Townsite	40,000	251,700
Temiskaming	.....	808,620
Temiskaming & Hudson Bay	240,000	1,460,500
Trethewey	.....	1,910,476
Watts	.....	561,680

*Concentrates. **Concentrates and high-grade ore.

The total shipments for the week were 1,398,990 pounds, or 699 tons. Total shipments from Jan. 1 to date are 34,429,473 pounds, or 17,215 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, Sept. 26.—The following are the ore shipments from the mines of the various districts of Southeastern British Columbia for the past week and year to date:—

	Week.	Year.
Bundary	38,239	1,008,100
Rossland	5,478	203,699
East of Columbia River	1,845	73,135
Total	45,562	1,284,943

Following are the shipments from the various mines and receipts at smelters of the districts of Southeastern British Columbia for the week ending October 3, and the year to date:—

Boundary shipments—	Week.	Year.
Granby	21,681	786,852
Mother Lode	10,578	171,777
Oro Denoro	217	49,886
Snowshoe	2,249	9,124
Other mines	Nil	22,248
Total	34,778	1,039,877
Rossland shipments—		
Centre Star	4,051	127,258

FOR SALE
Copper and Lead Mine

on Lake Superior, near Port Arthur, four hundred acres; old title; considerable development done; good mineral showings; bargain price; easy terms on working option. For further particulars, apply to

W. L. HIME,
160 Dowling Ave., Toronto

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary, and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

CLYDE PATENT WIRE ROPE WORKS

Rutherglen, Glasgow, Scotland

WIRE ROPES

For Winding and Haulage in Collieries and Mines, Aerial Ropeways, Transmission of Power, Suspension Bridges, etc. SPECIALLY FLEXIBLE ROPES for Hoists, Winches, Loading and Discharging Cranes, Shipping Purposes, Towing, Alligator and Dredger Ropes, etc. SPECIAL ROPE FOR LOGGING.

Our Ropes are made from wire drawn for our exclusive use, and are at work all over Canada. Messrs. Nova Scotia Steel & Coal Co., Ltd., who use them largely, write that one of our haulage ropes at their Wabana Mine has been in use for **5 years**, drawing over 1,750,000 tons and still in good condition. From the Atlantic to the Pacific they are well known and our agents will be only too pleased to give all information to enquirers. They may be had from the following, viz:

Nova Scotia: Wm. Stairs, Son & Morrow, Limited. **New Brunswick: W. H. Thorne & Co., Limited.**
Montreal and Toronto: Drummond, McCall & Co. **Vancouver, B.C.: John Burns.** **Winnipeg: David Philip, Portage Ave.**

HIGHEST Quality. MODERATE Price. Prompt Delivery. SATISFACTION in use.

Cables: "Ropery, Rutherglen." Codes: A. B. C. (4th and 5th Editions), A.I., Liebers and Private.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

NOW READY

Contains all the latest information up to within a few days of publication. The Standard Reference Work on Mines. 1,600 pages. In demy 8vo, cloth. Price 21/-, post free.

The book can be seen and obtained at the Offices of this paper.
Twenty-Second Year. Established in 1887.

The Mining Manual
For 1908
By WALTER R. SKINNER

22nd YEAR

A Record of Information concerning Mining Companies (Gold, Diamond, Silver, Copper, Tin, Iron, and other Mines, Collieries, Land, and Exploration Concerns, etc.)

Arranged in Three Sections, **Australasian, African, Miscellaneous,** with Tables of Crushings at ends of Sections, followed by List of Mining **Directors and Secretaries,** their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected; also **Mining and Consulting Engineers and Mine Managers,** with their Company connections, and a **Dictionary of Mining Terms.**

THE MINING MANUAL FOR 1908 contains particulars of no less than 3,100 COMPANIES, arranged in three sections, 450 Companies being AUSTRALASIAN; 1,050 AFRICAN; and 1,600 MISCELLANEOUS (including Siberian, Mexican, Indian, Canadian, American, etc., and the Coal, Iron, and other mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; position at mine and ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts.

The Lists of Directors (over 7,000) and Secretaries (1,750) include their addresses and descriptions and names of the Companies with which each particular Director or Secretary is connected.

A complete Alphabetical Index, including many useful items of reference, occupies 40 pages.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

The JEFFREY
26-B "SHORTWALL"
ELECTRIC COAL CUTTER

For room and pillar work on the Longwall plan

It cuts faster, consumes less power per cubic inch of coal cut, occupies less space, permitting the props to be set closer to the face of the coal, is more easily controlled, operated and handled, is simpler and has greater strength, motor power and endurance

Than any other make of SIDE CUTTING MACHINE

This machine is loaded, unloaded, moved to and from the coal face and in fact handled throughout by its own power.

FULLY DESCRIBED IN BULLETIN No. 14

THE JEFFERY MFG. CO., Columbus, O, U.S.A.

NEW YORK KNOXVILLE CHICAGO CHARLESTON BOSTON PITTSBURGH ST. LOUIS DENVER MONTREAL

"Continuous Coal Cutters"

Sullivan Continuous Coal Cutter in Byesville, Ohio, Field, showing method of cutting across the face

The Sullivan Room and Pillar Chain Machine has an efficiency of 50 to 200 per cent. in excess of the breast machine, owing to the following facts:

1. Machine cuts across entire face in one operation without moving tracks or barring machine by hand.
2. Occupies one half as much space in front of coal. It is not necessary to move props when using this machine. Props shown in cut are 6 feet from face of coal.
3. Machine cuts high kerf, cuts on the bottom, and leaves no coal to be lifted, nor spragg or rib at seat of cut to hinder blasting.
4. Uses from 20 to 30 per cent. less power per ton of coal cut.

GOOD HUNTING

The finest hunting grounds in Canada—for big game and small game, are reached by the Canadian Pacific Railway. Amongst the best must be reckoned the country adjacent to the recently opened Toronto-Sudbury line—alive with moose, deer, bear and every variety of game. This will be the first Fall this country has been accessible by rail. Go up while the hunting is at its best.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

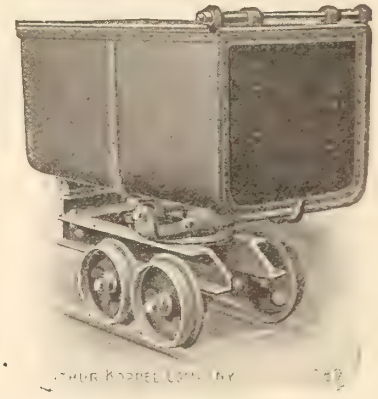
The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.



WRITE US FOR DESCRIPTIVE PAMPHLET.
FORWARD SAMPLE OF YOUR ORE FOR PRELIMINARY TEST.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLER

Provincial Geologist of Ontario, formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

SUBSCRIPTIONS—Payable in advance, $2.00 a year of 24 numbers, including postage in Canada. In all other countries, including postage, $3.00 a year.

Advertising copy should reach the Toronto Office by the 8th, for the issues of the 15th of each month, and by the 23rd for the issues of the first of the following month. If proof is required, the copy should be sent so that the accepted proof will reach the Toronto Office by the above dates.

CIRCULATION.

During the year ending with March 1st, 1908, 91,750 copies of "The Canadian Mining Journal" were printed and distributed, an average of 3,822 per issue.

"Entered as second-class matter April 23rd, 1908, at the post-office at Buffalo, N.Y., under the Act of Congress of March 3, 1879."

SPECIAL CONTRIBUTORS.

Geology: Dr. Frank D. Adams, McGill University; Dr. A. E. Barlow, late of Geological Survey of Canada; Professor Willett G. Miller, Provincial Geologist of Ontario; Dr. J. E. Woodman, Dalhousie University, Halifax, N.S.

Chemistry: Dr. W. L. Goodwin, Director School of Mining, Kingston, Ontario; Milton Hersey, M.Sc., Official Analyst Province of Quebec.

Mineralogy: Professor W. Nicol, School of Mining, Kingston, Ontario

Mining: S. S. Fowler, M.E., Nelson, B.C.; Frederick Keffer, M.E., Anaconda, B.C.; A. B. Willmott, M.E., Sault Ste. Marie, Ont.; J. C. Gwillim, M.E., School of Mining, Kingston, Ont.; J. Obalski, Inspector of Mines, Quebec; J. Bonsal Porter, M.E., McGill University; H. Mortimer-Lamb, Sec. Can. Min. Inst.; John E. Hardman, M.E., Montreal; Fritz Cirkel, M.E., Montreal; George W. Stuart, M.E., Truro, N.S.

Metallurgy: Stafford F. Kirkpatrick, School of Mining, Kingston, Ontario; A. P. Scott, Dominion Iron & Steel Company, Cape Breton.

Natural Oil and Gas: Eugene Coste, M.E., Toronto, Ont.

STEEL AND COAL.

Some time ago we alluded to the lamentably personal tone of the quarrel between the Dominion Iron & Steel Company and the Dominion Coal Company. More recently we pointed out that the Dominion Coal Company, through its president, had made definite overtures in the direction of a peaceful settlement, and that these had been rejected by the Dominion Steel people with but scant show of courtesy. Not only was this the case, but, possibly with the object of displaying their entire confidence in an ultimate victory, the Dominion Steel directors have failed to put forward any adequate counter-offer.

As bearing upon one of the most important phases of the Dominion Steel Company's arguments, we recommend to our readers' attention the article in this number of the Canadian Mining Journal describing Dominion Colliery No. 6. Mr. Gray touches upon the "Phalen seam" controversy. Our readers may judge for themselves as to the conclusiveness of the facts as there adduced.

Instances such as the "Phalen seam" dispute, in the light of later developments, prove the unreason of all such costly lawsuits as that of Steel vs. Coal. Whether Dominion Coal or Dominion Steel was to blame originally is insignificant in comparison with the urgent question as to why the dispute was allowed such a protracted existence. The country at large has an indisputable right to demand an answer to this.

The moment that quarrels of this kind, involving directly and indirectly many millions of dollars, reach the courts and high-priced legal lights are engaged to fight the case out, an amicable and equitable settlement becomes almost impossible. It is our firm belief that such quarrels should be taken entirely out of the hands of hot-headed principals and referred at an early stage to a properly constituted Conciliation Board, a body analogous in most respects to that which deals with difficulties between employers and employed, but clothed with absolute power to give a final and binding decision. Had such a board been in existence Canada would have been spared two years of undignified bickering.

MODERN STAMP-MILLS.

A South African stamp-mill, which commenced crushing in September, is notable in several respects. The mill framework is constructed of steel. The battery is driven in units of five stamps by individual motors. There are 300 stamps. Each stamp weighs 1,750 pounds.

Steel construction for large stamp-mills is now an established practice. Self-contained units, in which

the cumbrous cam-shaft of the past is replaced by one that does duty only for five or ten stamps instead of twenty or thirty, are logical necessities. Repairs are lessened and lightened. A break-down involves only the unit concerned, and great flexibility is attained in large installations.

Not only do these changes facilitate the every-day running of the mill, but they also make the mine manager's work lighter. Parcels of ore from different parts of the mine can be treated separately without loss of time, and on all the ore crushed a closer watch can be kept. Incidentally also there is a great saving of power in any such system of controllable units.

MIND AND MATTER.

Secular education has made giant strides in latter years. The principles of evolution have been accepted by scientist and theologist alike, as the foundation of modern knowledge. Geology, chemistry, theology, have become but naked equations. The mighty groanings and laborings of Mother Earth have been measured, recorded, and analyzed. We know that certain climatic and certain physiographic environments produce Anabaptists, that others bring forth Mahometans. Here, the Heresy-trial will flourish; there, the Inquisition.

And so we are filled with conceit of ourselves. In our pride we forget that there be many things of which we have but dim knowledge.

All of which leads to the recital of a tale that is worth telling—a tale that proves that man in his direst need must depend not upon books or brains or muscle, but upon a psychic something that is latent in all of us, developed in but a chosen few.

Upon another page is recorded the progress of that flying squadron of excursionists, which, piloted by the Canadian Mining Institute, traversed so recently our fair Dominion. Mines, quarries, furnaces, they visited. With them went one free-born citizen of Cobalt.

At a town called Calgary an hospitable rancher seized upon the pilgrims and bore them to his ranch, where, for their edification, he had caused a bronchobusting, steer-lassooing tourney to be held. Now the tourney proper was confined to a large enclosure, whose limits were marked by a high barbed wire fence.

After due busting of bronchos the steer-lassooing began—also the trouble. The guests, men venturesome and intrepid in shaft or drift or smelter, were looking now upon strange doings. The danger of the unknown brought them together, and they congregated near the entrance of the corral.

Without a warning, like an overdue creditor, a steer wide of horn and unspeakably fierce of mien, eluding cowboys and busters, sought to do some busting on his own account. Then horrid was the sight. Bulky Teuton, stolid Briton, austere Austrian, surly Scot, impaled himself upon that barbed fence. But the Man from Cobalt, captain of his soul, master of his emotions, shinned a seven-foot fence post and gazed serene upon the tumult below. Not long was he serene. That steer, blood in his eye, slaughter in his wicked heart, charged. Blinded with blackest passion, he hurtled into—not foreign dignitaries and international complications—but into and through the barbed wire.

Now the perch of the Man from Cobalt was precarious at best. Good living had increased his diameter, widened his cross-section. Thus it befell that the impact of that impetuous steer upon the fence loosened our hero's hold and shook him, not unlike an overripe plum, to the ground. And now behold him, recumbent, dazed, helpless, facing the horn-tossing beast! Did the Man from Cobalt blench? Did he quail? Did an ague of fear seize him? Not so! Calmly, intently, he fixed that animal with his luminous eye. Slowly, but surely, under the mesmeric power of that eye, the steer became less hostile, and at last, resuming his neglected cud, turned and went his way.

Such is the simple narrative of one great victory. We feel a spiritual glow, a lofty joy, in the knowledge that Cobalt produced the victor.

THE HON. MR. TEMPLEMAN.

There are considerations that override all questions of politics. On one of these we wish to touch.

The Hon. William Templeman was Canada's first Minister of Mines. The Department of Mines, created a little more than a year ago, has already, under Mr. Templeman's direction, accomplished much. But more has been planned.

The Minister of Mines, accompanied by the Acting-Director of the Geological Survey, R. W. Brock, has recently completed a tour of inspection of Ontario and British Columbia mining districts. We have reason to believe that similar tours through Quebec, New Brunswick and Nova Scotia were to have been undertaken. This is but an incident. But it reveals the fact that the Hon. Mr. Templeman is keenly interested in the mining industry and is anxious to see things for himself. Moreover, the Hon. Mr. Templeman has won and held the confidence not only of the officers of his department but of Canadian mining men.

As a result of the election, Mr. Templeman is now without a seat in Parliament. We hope most sincerely that this will not mean that he will no longer serve as Minister of Mines. We are sure that the Premier is sufficiently cognizant of the need there is of honest, competent and enthusiastic work in directing a department whose importance is growing day by day. The Hon. Mr. Templeman's work speaks for itself. A break in its continuity would be particularly disastrous. Any step that will insure the return of the Hon. Mr. Templeman to the position of Minister of Mines will be heartily welcomed by the Canadian Mining Journal.

and, if we are not mistaken, by all Canadians interested in the development of the mineral industry.

TAXATION OF MINERAL RESOURCES

Discussion of this vexed subject usually results in dithyrambs or expletives. We recall vividly certain delegations that waited upon a provincial minister of mines; and we remember thinking of the story of the Tower of Babel as it is recorded in Holy Writ.

We are glad to present in this number of the Canadian Mining Journal, a vigorous and suggestive paper on the taxation of mineral resources. Mr. Skelton is not unknown to the reading public. As the successor of Professor Adam Shortt in the chair of political ecenomy at Queen's University, Mr. Skelton occupies a position of more than academic importance.

Mr. Skelton's views are set forth with freshness and force. His subject is complicated and difficult. But he has wisely attempted to get down to bedrock, to make sure of whatever foundation there may be. In this respect he has rendered valuable service by clearing away incidental and accidental material that heretofore has blocked the view of those most interested in the subject.

It is beyond contradiction that Canadian mining men have either given the question of mine taxation too little consideration or have allowed purely local conditions to color their opinions too strongly. The matter is one that demands broad and careful treatment. Above all it is necessary that the recommendations made in the name of our representative society, the Canadian Mining Institute, be made not in the heat of debate, but only after lengthy deliberation.

We hope that Mr. Skelton's excellent paper will arouse renewed interest in a topic that should not be permitted to grow stale.

COAL DUST EXPLOSIONS.

The conclusions adduced by Messrs. James and John Ashworth in their paper on coal dust explosions are particularly important.

For some time watering was advocated as a panacea for all coal-dust ills. It was recognized, however, that where the mine temperatures were high, watering rendered work impossible. Next it was established that, in the presence of coal-dust, a damp atmosphere is more dangerous than a dry atmosphere.

Moreover, the best of flameless explosives may become the immediate cause of coal-dust explosions. The Messrs. Ashworth have ample ground for their dictum "that it is not possible to use any known explosive with absolute safety in a gaseous mine."

Here, however, the use of minimum quantities of explosion for each shot fired offsets the danger.

These, and many other considerations, point to the necessity of close and complete investigation of all the phenomena attending coal-dust explosions. And the most intelligent method of attacking the subject is, we think, that of beginning at coal-dust itself. That coal-dust must be considered as made up of particles enveloped and saturated with gases, is a much more logical position than that which defines coal dust as a aggregation of small solid particles.

We are in hearty accord with the object of the Messrs. Ashworth's paper. It is intended as an outline of the problem from a practical, working point of view. It presents the subject in a manner calculated to inspire interest and provoke discussion. And free discussion will most effectually dispose of the mischievous fallacies that have heretofore hindered investigators.

A writer in Queen's Quarterly makes unkindly comments upon Mr. T. A. Rickard's book, "A Guide to Technical Writing." The critic's objections are numerous. He states that the book will never serve as a text-book on "composition even among science students. . . . It deals too much with details." The Quarterly critic is at sea. "Composition," as it is learned from text-books and as it is taught in public schools, is a ghastly thing. Mr. Rickard's book is valuable because it is interesting from cover to cover, and because it deals with details.

THE TAXATION OF MINERAL RESOURCES IN CANADA

By O. D. Skelton, Queen's University.

(Read before the International Tax Conference, Toronto, October 8th, 1908.)

The taxation of mineral resources is, from the nature of its object, of less universal appeal than any other phases of the fiscal question. Everywhere men own houses and lands, mortgage property, and bequeath estates. But it is in only a minority of the commonwealths on this continent that the posession of rich mineral deposits affords the budgetmaker an opportunity and a problem.

On this side of the line at least there is general agreement that the opportunity should be improved, and the mineral wealth of the nation be made in some form or other to pay toll to the treasury. A plausible case has been made out for state ownership and operation, especially in the case of coal mines, but such a proposal involves a further advance toward paternalism than our American conditions and requirements warrant, at least as a general policy. A recognition of the inexpediency of public ownership does not, however, necessarily entail the adoption of the policy of granting mineral lands in fee simple on nominal terms. The considera-

tions which have made it seem advisable, throughout the greater part of the continent, to grant agricultural lands outright to the settler, practically without payment, do not bulk so important in the case of mineral lands. Granting leases for a fixed term of years in return for rental or royalty payments, is an intermediate policy which has much in its favor, and is, in fact, the policy prevailing in some of the most important Canadian fields. If again we reject this compromise as not sufficiently attractive to the prospector and the promoter, and hand over the mineral heritage of the commonwealth to individual exploitation, there certainly remains a good prima facie case for demanding a share through the ordinary channels of taxation. Granting that mining is a lottery in which the prizes rarely reach the price of the tickets, there seems no valid reason why the prize winners should not contribute their quota to meet the needs of government, subject, of course, to the same qualification as in other lines—that the tax should not be so excessive and indiscriminate as to deter investment nor the mode of collection vexatiously hampering. Nor is there much disagreement that mineral resources should be reserved for state rather than for local taxation. Whatever abstract basis of taxation we choose, whether domain-right or benefit or the good old Jack Sheppard basis of faculty, it is manifest that the wider unit has the greater claim. Decisive in the same direction is the consideration that if an adequate tax were imposed by a municipality it would often far exceed its legitimate needs, and if, on the other hand, the tax were cut to suit the municipality's normal expenditure, the industry would escape paying its fair toll. More contentious and of more practical importance are the questions how, and how much, to tax. With the purpose of setting forth Canada's contributions to these problems I shall review briefly the measures adopted in the sections where mineral taxation provides an important part of the revenue.

To begin with the province in which we are assembled—Ontario. As you are doubtless aware, the sources of provincial and local revenue are in the main quite distinct in Canada, unlike in the United States. Ontario derives its revenue chiefly from a Federal subsidy granted in lieu of the customs revenue surrendered at Confederation, from succession duties, corporation taxes and licenses, and from timber dues, and mining taxes, sales, and fees. The existing mining policy is of very recent origin, coincident, in fact, with the Cobalt boom. Twice in the history of the province the growing prosperity of the mining industry has led to the imposition of taxation, and twice repeal has followed on its decline. So recently as 1900 the late Provincial Government decided to grant mineral lands in fee simple, free from all reservations, and abolished the existing royalties, which varied from 2 to 3 per cent. In 1906, when the Mines Act was revised, the present Government confirmed this action, on its negative side, taking the ground that the impairment of title involved in the lease-royalty system deterred investment. But there was no intention on the part of either the Government or the people, dazzled by the new-found wealth of Cobalt, of foregoing such a promising source of revenue; it was only desired to change the form of sharing. The popular demand for action was the more insistent because it was through the building of a Government railroad that the silver field had been discovered, and largely by the aid of Government officials that it was developed. The further fact that the indirect benefits received were less than usual, owing to the cost of working, the Cobalt deposits being extremely low, and the ore being nearly all shipped out of the country for treatment, made the case overwhelming. It was largely, it is to be noted in passing, the Cobalt and Copper Cliff properties that apparently were in mind when the tax measures were framed, a fact not without significance for other less spectacular, struggling branches of Ontario's mining industry.

Action took several different lines. Most radical was the determination to reserve and develop for the province a promising tract, containing three and one-half square miles, in the Gillies limit, which had been withheld from prospecting on account of the timber operations on the surface. The provincial mine is being developed in the most scientific manner, and it is hoped that the only Government-owned and operated mine on the continent will prove a large source of revenue. Ontario has shared in the wave of public ownership sentiment, which has steadily been rising in America for the past few years, so that this step met with almost unanimous approval: public ownership has a romantic glamor when it is a silver mine which we, the people, control, lacking when the more prosaic gasworks or street-car line is concerned.

In various other cases where veins were found on the right of way of the Government railway, or where claims were in litigation, special bargains were made on the basis of a cash bonus, together with a royalty of varying amounts. The bed of Cobalt Lake was sold for $1,085,000, of Kerr Lake for $178,500, and a royalty of 10 per cent.; the O'Brien and Crown Reserve pay a royalty of 25 per cent., while the Government railway, the Temiskaming and Northern Ontario, has made similar royalty agreements, usually on a 25 per cent. basis, with companies controlling the City of Cobalt, Cobalt Townsite, and Right of Way. These royalties, it is to be remembered, are not instances of a general scheme of taxation, but merely portions of the purchase price of claims sold under exceptional circumstances. Over and above the royalties paid, these mines are subject to the general tax about to be noticed.

Taxation proper forms the third source of mining revenue in Ontario. The basis laid down in the Act of 1907 is net profits. All mines which yield an annual profit above the exempted amount of $10,000 pay a flat rate of 3 per cent. on such excess. In ascertaining the profits, the gross receipts, or value at the pit mouth, is taken, and from this sum is deducted the cost of transportation of output sold, if borne by shipper, and actual working expenses, including mine wages and salaries, cost of fuel, of explosives, power, insurance, and sinking new shafts, and an allowance for depreciation of the plant—not of the mine. The tax levied in any year is based on the profits of the preceding year. Detailed statements are required for every operator, subject to check by the Mine Assessor, who is vested with wide powers of investigating both mine and books. Provision is made for appeal against the assessment of the Bureau of Mines to the Ontario Railway and Municipal Board, or to the Mining Commissioner, and if more than $1,000 is involved, a final appeal may be taken to the Ontario Court of Appeal.

Natural gas is taxed two cents per 1,000 feet, based on the company's books, or, if the Mine Assessor considers it advisable, on meter records. This, however, is virtually an export tax, as 90 per cent. of the tax is remitted if the gas is consumed in Canada, while gas used by municipalities is entirely exempt. Similarily in

the case of iron ore smelted in Canada, the profits tax is entirely remitted. In addition, an acreage tax of two cents per acre is imposed on all mining claims in unorganized portions of the province, above ten acres in extent, including mining rights held separately from surface rights. The final source of income consists of fees for prospectors' licenses, claim-staking, recording and transferring claims, etc. Mining companies, as well as individuals, are required to hold a miner's license, the fee varying with the amount of capital stock, but not exceeding $100.00 per million of capitalization.

It may be interesting to sum up the provincial revenue from mining sources in 1907; it comprised:—

Sales of mining lands		$1,184,719 06
Leases		21,563 16
Miners' licenses, recording fees, &c		272,937 13
Royalties		207,945 06
Supplementary Revenue Act, 1907.		
Taxes on natural gas	$11,527 47	
Taxes on profits	26,922 00	
Acreage tax	5,003 88	
		$43,433 35
Assay Office (Belleville)		1,642 96
Total		$1,731,720 72

It should be noted that this was an exceptionally heavy year. The largest item, sales of mining lands, includes over a million dollars on the Kerr Lake and Cobalt accounts, and is not likely to be duplicated. On the other hand, the taxes under the Supplementary Revenue Act are based on the 1906 production, and will be much larger in succeeding years.

A word or two on the relations between provincial and local taxation. The Ontario Assessment Act provides that municipalities shall assess mineral lands, except oil lands, only at the value of other lands in the neighborhood for agricultural purposes; plant and equipment may be assessed at full value. Income derived from mining properties is, however, subject to municipal taxation in the same manner as other incomes. Contrariwise, in assessing the profits tax to be paid to the province, permission is given to deduct income tax paid municipalities, if not exceeding one-third, or in one specific instance, one-half, the total due.

The systems of taxation prevailing on the other districts must be summarized more briefly. Quebec and New Brunswick have rich mineral resources, but in neither case has development, especially of metallic minerals, proceeded far enough to warrant extensive taxation. Nova Scotia, however, possesses thriving coal and gypsum industries, a declining gold industry, and a subsidized iron industry. Mining taxation is an important source of its revenue, providing over 40 per cent. of the provincial income. Nova Scotia still adheres to its traditional policy of granting only leases of its mining lands, deriving a revenue chiefly from rentals and royalties. On gold a royalty of 2 per cent. of the gross value of the output is levied, collected from the stamp mills. The rental and royalty on gold amounted last year to about $13,000. Of much greater importance is the coal royalty, 10 cents a ton, excepting in the case of the Dominion Coal Company, which in 1893 obtained a 99-year lease of about 150 square miles on a 12-cent royalty basis. The royalty collected last year on a production of 5,700,000 tons was $563,000, or about 5 per cent. of the gross value of the output. Other license and rental fees brought the total to $633,000.

At the other side of the continent British Columbia contests with Ontario for primacy in mineral production, chiefly gold, silver, lead, copper and coal. The same policy prevails in granting lands in fee simple. The western province has not sought to swell its revenue by developing provincial mines or making million-dollar sales, but its system of taxation is comprehensive and well devised. A general tax is levied on minerals, other than coal, 2 per cent. of the gross, not the net, value of the output; ore-producing mines yielding less than $5,000 a year are granted a refund of half the tax, while the placer mines yielding lass than $2,000 are exempt entirely. On coal there is a tax of ten cents per ton, and fifteen cents on coke, if produced from untaxed coal. Until last year the rates were five and nine cents respectively. Unworked coal lands are taxed 2 per cent. on the assessed value, and an acreage tax of 25 cents per acre is imposed on unworked Crown-granted mineral claims. These taxes, together with the usual fees, brought in over $580,000 last year out of a total provincial revenue of $4,440,000.

The Federal Government also receives a share of mineral taxation. In the Provinces of Alberta and Saskatchewan, where the Dominion retains the Crown lands, a royalty of five cents per ton is collected on the coal, which, especially in Alberta, is being mined in rapidly growing quantities. The Yukon, which, as a territory, is still under Federal control, also yields a fair return to the Dominion. While its bonanza days are over and the production of gold has dwindled from $22,000,000 in 1900 to one-fourth of that sum last year, there is still good prospects of work on large scale, in dredging and quartz mining. The rate of taxation levied by the Dominion has decreased about as rapidly as the production. In 1897, to recoup itself for the heavy expenditure for road-building and policing caused by the Klondike rush, the Government imposed a tax of 10 per cent. on the gross value of the output up to $500, and above that 20 per cent. In the spring of 1898 the tax was made uniform at 10 per cent., with an exemption fixed at $2,500. As the levy was based largely on voluntary returns, it is no wonder that the high rate of taxation prevailing there was much evasion. In the year 1900, for example, the production was $22,375,000, according to the figures of the Bureau of Mines, based largely on reports of the Seattle and San Francisco assay offices. Yet the royalty collected for the fiscal year of 1899-1900 was only $730,000. If one-third the total output were conceded to fall under the $2,500 exemption, the royalty collected should have been fully twice as great. Accordingly, in April, 1901, the rate was halved and the exemption doubled, and finally in May, 1902, the present system was adopted. A tax of 2½ per cent. is now levied on all gold shipped out of the territory, the exemption, of course, being abolished. The practice is to sell the gold to one of the banks and trading companies at Dawson for drafts on other Canadian or American cities. The bank, which has deducted the amount of the tax from the purchase price, pays the export tax on shipping out the gold. Close inspection is made at the boundary to prevent smuggling out uncertificated gold. The new system has proved much more satisfactory in operation.

Some brief comments on the legislation reviewed may be in order. It will be noted that in practically all cases the tax is based on the value of the product rather than on the capital value of the mine. In the "Outline of a

Model System of State and Local Taxation," presented to the conference last year by the Vice-President of this Association, it was recommended that mineral taxation "should be imposed wherever possible, upon the capital value, excluding the value of the surface. If for any reason this is not practicable, the tax can be imposed in the form of a royalty." In Canada the order of preference is just the reverse. The negative reason for this is found in the fact that our constitution leaves more scope for legislative discretion than the American State constitutions. As our cabinet system of government makes it possible to fix responsibility more definitely, we feel free to grant power more freely, assured that all will be well, so long as, in Palmerston's phrase, there is someone to hang. This results sometimes in short cuts to justice, as, for example, in the Ontario Government's handling of various Cobalt disputes, which would send a shudder through the American trained in awe of rigid constitutions and courts committed to outworn economic shibboleths. In the field of taxation this freedom means that the Legislature is not forced either to conform to constitutional limitations in the vain striving after the uniformity of the general property tax, as in Minnesota, or to evade them by having recourse to license or franchise taxes, as advocated in West Virgiain.

The positive reason for preferring a tax on output is its greater certainty and definiteness. Any estimate of the value of minerals still in the ground, such as that just completed by the Minnesota Tax Commission, must, it is felt, contain a large element of guesswork, diligent and scientific guesswork it may be, but guesswork still. Greater exactness may be imparted to such ad valorem estimates by taking account, among other data, of the annual output, net or gross, and capitalizing this amount; but it is evident that this is so far merely an indirect return to the annual product basis.

The Canadian provinces have been less unanimous in deciding whether to tax on gross or on net annual production, as the outline given has shown. There are obvious objections to taxing net profits. From the point of view of the taxing authority, the first objection is that if in any year there chances to be no net profit, the mine or industry in question escapes taxation entirely, a privilege not open to the farmer whose crop has failed or the merchant whose trade has been dull. This is a real difficulty, but its importance is less in mining than in railroading, for example, since the mine is less likely to be operated than the railroad when expenses cease to be met. The second objection, from the same viewpoint, is the danger of the books being doctored to make the net returns appear as small as possible. This, again, is a very real difficulty. It can be met, however, by the adoption of a uniform system of accounting. If some such system as that which the British Institute of Mining and Metallurgy is endeavoring to draw up were made compulsory, the Mine Assessor's task would be lightened. From the point of view of the industry taxed, objection is raised against the inquisitorial powers conferred on the Mine Assessor, with all their possibilities of abuse. On this point some light may be thrown by the following quotation from a letter from one of the most prominent mining men of the province: "One can easily see how the net profits tax gives opportunity for any amount of graft and fraud on the part of the Assessor, an opportunity for first knowledge of the financial positon of the different properties, and of working the stock market to his advantage accordingly. As a matter of fact, however, owing solely to the high character and efficiency of the present Mine Assessor, who happens to be so fair-minded and honorable a gentleman that he has met with the approval of the great majority of the mining men, the enforcement of the machinery for collecting the tax, has not, I think, proved unbearable." If then, by a satisfactory solution of the personal equation, and the adoption of uniform accounting, the main objections to the net profits tax can be overcome, it seems on the whole preferable to the tax on gross value, because of its greater fairness in allowing for differences in expense of working, between one mine and another. The British Columbia mineral tax on net smelter returns, which does not make such allowance, obviously bears hard on low grade properties, while its coal tax is a more serious burden on Rocky Mountain than on tide water producers.

Much less deserving of consideration than the men engaged in actual development are the speculator who hold claims undeveloped for decades, and the syndicate which blankets large areas to prevent competition. The extent of this problem is evidenced by the fact that while, in 1906, 1,300,000 acres of mineral lands had been patented in Ontario, only a small fraction was being worked. Quebec's mining development has been hindered even more by similar conditions. The problem is one which would not arise in serious form if the policy of granting only leases of mining lands were followed, a policy which, as in the case of timber lands, though, of course, to a less degree, seems essential to the conservation of the future interests of the country. Though it is objected that the leasing policy discourages investment, it would appear that a 20 or 30-year lease on a fixed rental and royalty would be as attractive to the actual operators, if not to the promoters, as an outright grant subject to variations in the tax-rate every two or three years. If, however, the fee simple policy is adopted, taxation should be called in to remedy the inevitable evils. Ontario and British Columbia have grappled with the problem their generosity created, by imposing an acreage tax. As a result of the stricter execution of the Ontario law in 1906, over 300,000 acres were forfeited for failure to pay the tax of one cent per acre then imposed. It is the opinion of many mining men that the acreage tax should be very materialy increased. Perhaps the best plan would be to impose a graduated scale, the tax being made light for the first few years after acquisition, and bearing more and more heavily each year thereafter, till a maximum was reached, so that the holders would be compelled either to develop the property themselves or to make way for someone who would.

One remove further still from the man with the drill and concentrator is the promoter who never produces anything but beautifully engraved certificates. It is a frequent and natural cause of complaint of mine operators that while they are rewarded for developing the country's resources by heavy taxation, the shady promotor goes scot free. It does not, however, seem advisable to attempt to remedy the evils of fraudulent promotion by the slow-moving and indiscriminate machinery of taxation. Hope is to be found rather in strict enforcement of the provisions of the Companies' Act regarding prospectus publicity and directors' liability, and in journalistic vigilance.

A question of minor interest is raised by the exemption granted oil wells in Ontario's scheme of taxation

In favor of exemption it is urged that by permitting municipalities to tax oil lands at their real, instead of at their agricultural, value, the gap is closed. But, aside from the fact that the municipalities do not, as a matter of fact, tax this increased value, the argument advanced runs counter to the general policy of separating provincial and local sources, which is one of the best features in the Ontario system. Nor does the plea that oil is a necessity in every home and therefore merits exemption, carry conviction on this continent dedicated to protective duties on the chief necessities of life. Perhaps the omission may be justified on the principle *De minimis non curat lex,* as the total production for 1907 was less than 800,000 barrels, worth about $1,500,000 (natural gas reached about $750,000 in value), and the grade is so inferior that the Dominion Government considers it necessary to give a bonus of 52½c. per barrel to enable the industry to compete with the American product. Possibly if a provincial tax were imposed the Dominion authorities might be obliging enough to increase the bonus correspondingly.

Though somewhat of a digression from the subject of the paper, it may be worth noting here, as the reverse side of the picture just presented, of abundant inflow of revenue, the amount expended on bonusing mineral production. The total revenue received in Canada from mining sources in 1905-06 was slightly under $2,000,000. In approximately the same fiscal year the Dominion Government paid out in bounties to encourage the production of lead, petroleum and pig iron, and the manufacture of steel and steel products, over $2,380,000. Various minor provincial subsidies and exemptions, not to mention very low rates granted certain steel companies, on the Government railroad, the Intercolonial, brought the amount well over $2,500,00. It is not to the point here to consider how far these subsidies have served their purpose or how far they have simply given company promoters more excuse for watering stock, but you can see from this brief reference how fond we are in Canada of taxing Peter to bonus Paul.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

F. W. GRAY.

(*Continued from issue of August 15.*)

Dominion No. 6 Colliery.

No. 6 Colliery is the most recent of the six Phalen seam mines of the Dominion Coal Company. It is a slope mine placed at the eastern extremity of the Glace Bay Basin, and its territory is mostly submarine.

The crop was opened in the spring of 1904, and the mine began to be a regular producer about one year later. At the present time the output is 25,000 tons per month, which will be raised to 30,000 in 1909, at which time the new permanent haulage now in course of construction will be completed.

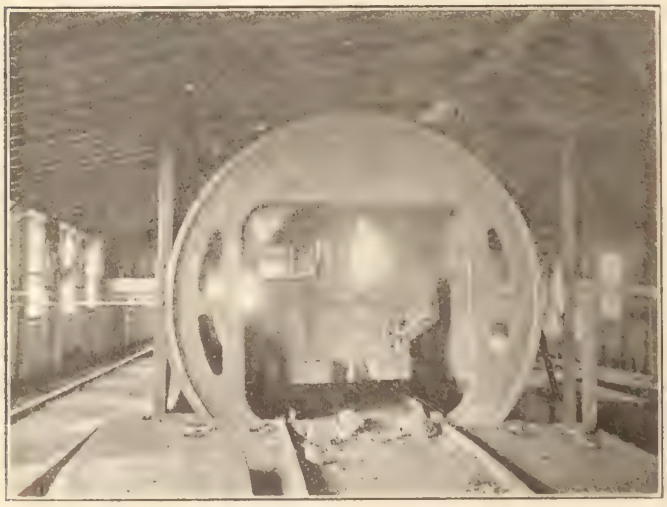
No. 6 Colliery came into a good deal of prominence at the time of the Steel-Coal trial before Judge Longley

No. 6 Colliery Bankhead and Compressor House.

in Sydney. One of the most surprising features of this trial was the extraordinary assertion of the Steel Company's counsel that the workings of No. 6 Colliery were not on the Phalen seam. For several days in succession the court at Sydney was treated to learned disquisitions on paleontology and goelogical horizons, illustrated by a large wooden model of the Glace Bay coalfield. To those who had any knowledge of the actual facts the evidence given on this matter was a delicious admixture of opera bouffe and burlesque, to which the innocent seriousness of the performers gave additional piquancy. To disprove the Steel Company's contention the Coal Company were put to the expense of sinking boreholes all along the shore line from Caledonia Colliery to No. 6 Colliery. The explorations resulted in a complete and absolute corroboration of the plans and sections of the Geological Survey of 1872-1874, establishing the fact that the workings of No. 6 Colliery are on the continuation of the Phalen seam. This should never have been questioned. Only the audacity of ignorance could excuse a contention so

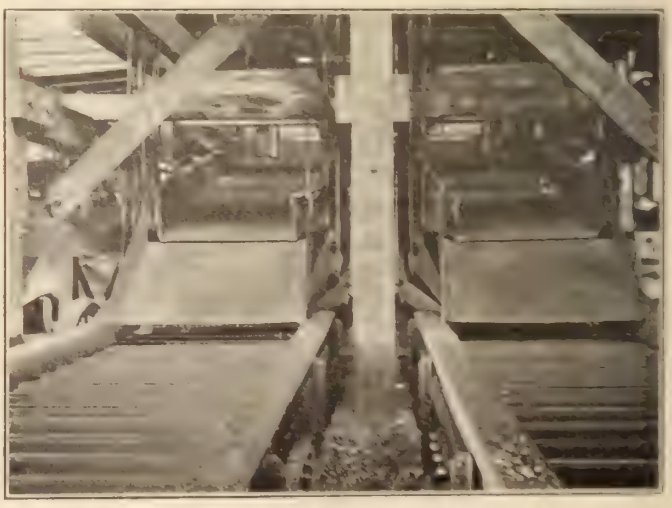
No. 6 Bankhead, Trestle Approach, Carry[illegible]

manifestly "frivolous and vexatious," and for ignorance, in view of the work of the Geological Survey, there was neither necessity nor palliation. This is very plainly shown by the remarks of Mr. Hugh Fletcher in his "Summary Report for 1907 on Explorations in Nova Scotia." Mr. Fletcher writes: "A few days spent in examining pits and boreholes between Glace



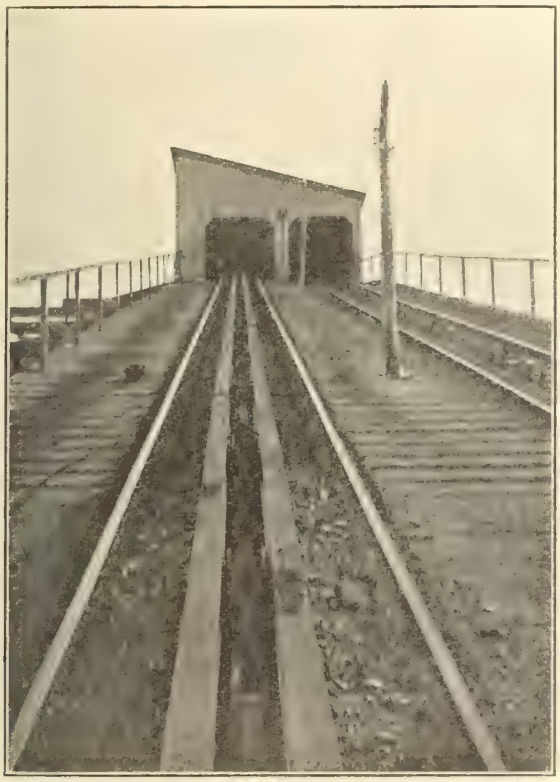
Bay and Schooner Pond convinced the writer that no mistake had been made in locating No. 6 as a colliery to supply the demand for Phalen seam coal, that the seam worked at No. 6 could be none other than the coal of the Clyde Mines and of McDonald Cove, called the Phalen; that the Emery seam is everywhere at its proper distance beneath it, and that, therefore, No. 6 cannot be on the Emery seam as had been suggested." After reviewing the evidence he had gathered in support of this statement Mr. Fletcher goes on to say that "it is not surprising that the writer should advise the Dominion Coal Company to desist from further explorations. My conclusions, which agreed with those communicated to the Dominion Iron & Steel Company in January, after consideration of all the official evidence on the subject, were again presented to the Dominion Coal Company." It will be remembered that the date of the Steel-Coal trial was August, 1907. In view of the fact that Mr. Fletcher's studied conclusions were placed before the officers of the Steel Company in January of the same year, comment is surely superfluous.

The surface buildings of the colliery and its equipment generally are of the most modern and substantial character, and provision has been made throughout for additions to the plant as the requirements of the colliery grow.



No. 6 Colliery—Interior of Compressor House.

The power plant at the present time consists of six Babcock & Wilcox boilers, rated at 1,500 hp., fitted with Parsons forced draft. The smokestack was built by the Alphonse Custodis Company of New York. It is 150 feet high, built of radial brick, on a common brick base. The boiler-house is of steel and brick con-



No. 6 Bankhead—Rotary Tipple.

No. 6 Bankhead—Picking Belts (Showing Screens)

struction, temporarily boarded up at one end to permit of a future extension of the boiler plant. An annex to the boiler-house contains the feed water heaters and feed pumps.

The compressor-house is a fine building, also of steel frame and brick construction. It is 90 feet

No. 6 Bankhead- Up and Down Car Hauls.

long, 63 feet wide and 30 feet high. It has massive concrete foundations, and is exceptionally well lighted and ventilated. It contains two Walker air compressors, 24x41 steam cylinders, 23½x38 air cylinders, and 48-inch stroke, having a total capacity of 7,000 cubic feet of air per minute. They are complete with circulation pump and after-coolers. They are fitted with an automatic lubricating system.

The bankhead is of modern design and almost entirely automatic. The structure is of wood, hard pine posts, spruce and hemlock framing on concrete pedestals, electrically lit, and fitted throughout with standpipes and hose for fire protection.

The coal cars are handled by automatic up and down car hauls, a revolving tipple, and an automatic "kick-back." The coal passes from the tipple on to a triple battery of shaking screens, from which it is fed to the picking belts, two in number. These belts are 43½ feet long, 6 feet wide, speeded to 43 feet per minute, and, as will be seen from the snapshots accompanying, they are exceptionally well lighted. The unusual width of the belts, the slowness of their motion and their general design are such that coal can be cleaned to the best advantage with the minimum of breakage. The nut and slack coal is dealt with by transverse swinging conveyors. It may be safely said that No. 6 has the most efficient screening plant in Cape Breton.

Up to the present time the haulage has been effected by a temporary hoist, which is being replaced by a 26x48-inch Corliss valve engine, built by the Jenckes Company. This engine will be large enough to overtake the haulage demands of the colliery for a long time to come. The foundations contain over 300 cubic yards of concrete. The engine-house will be of wooden construction, with a brick fire wall on the side next the pit.

Until quite recently the mine has been ventilated by a small temporary fan. This has been replaced by a Walker "Indestructible" fan, 20x7 feet, having a rated capacity of 300,000 cubic feet of air at 3-inch W.G. It is driven by a 16x16-inch Robb horizontal engine.

The fan itself is steel cased on concrete foundations, and the fan race is also constructed of concrete. The fan engine-house is of entirely fireproof construction, built of brick, lighted by metallic fire-proof windows, and roofed with corrugated asbestos sheating.

Other surface buildings are the machine shop, blacksmith shop, colliery warehouse, office, lamproom, washhouse, stables, firemen's hall, emergency hospital, etc.

The machine shop is fitted with a 23"x16' Porter lathe, steam hammer, pipe threader, and various machine tools. The equipment is very complete, as No. 6 is a considerable distance from the main shops at Glace Bay.

For fire protection purposes a 500-gallon Knowles pump is provided, and a sufficient equipment of fire-fighting appliances. The mine has its own fire brigade. It has also two corps of men trained to use the Draeger apparatus, four of which are kept at the colliery.

Safety lamps are exclusively used, all of the Ackroyd & Best type.

The mouths of both slopes are protected by reinforced concrete arches. The pitch of the Phalen seam at No. 6 is a little greater than the average of this seam in the other collieries, being around 12 per cent. The main deeps are down 4,000 feet, and are extended 200 feet beyond the shore line. The cover at the shore is 375 feet, and two levels are now being driven in submarine territory. On the west side of the mine the levels are rapidly approaching the workings of the Old

No. 6 Bankhead—Picking Belts (Beginning of Loading Arm).

Clyde Mine, which was worked years ago, and lies about midway between the workings of No. 6 and No. 4 (Caledonia). The Phalen coal from the Old Clyde Mine bore an excellent reputation for quality.

No. 6 is connected by a branch line 5½ miles long

with the main line of the Sydney & Louisburg Railway, which runs a passenger train twice weekly between Glace Bay and No. 6 for the convenience of the residents. The village consists of about 130 houses owned by the company. They are situated near the shore, and command a good view of the opposite coast and the mines of Glace Bay.

The next article of this series will deal with No. 2 Colliery, and this will complete the description of the Phalen seam mines in the Glace Bay Basin.

THE PRESENT POSITION OF THE COAL DUST PROBLEM.

By Messrs. James and John Ashworth, Mining Engineers.

(Paper read before the Victoria Meeting of the Canadian Mining Institute.)

The subject of coal-dust is still one of the most important questions which can be discussed by any meeting of mining engineers, and it, therefore, deserves very careful and detailed treatment, but for the purpose of the present meeting and for the useful advancement of information on this particular subject, the authors have condensed their matter so as to provide ample scope for the discussion of possibly every phase of coal-dust theories.

At the outset it may be of advantage to state what we mean by "Coal-Dust," as connected with colliery explosions—generally speaking, therefore, when they refer to coal-dust they will have in mind the very fine dust which is ordinarily present in coal mines and continuously produced from the coal in course of transit from the working face to the pit shaft by friction and that such dust is more dangerous than the older dust which has settled on the sides, roof and timbering of the mine.

We submit the opinion that this dust is the most dangerous factor in all collieries, particularly where firedamp is produced, and think that the many disasters which have occurred in Canada and the United States of America, are sufficient in themselves to take as examples, to convince every careful observer and student of coal-dust phenomena, that terrible disasters such as Monongah and Darr were mainly due to the part played by floating coal-dust, and that the incomplete combustion of this dust, coupled with the heat due to the pressure developed, acting on the older dust, created the huge volume of carbon-monoxide gas which is the actual life destroying element of every collinery explosion. To make our views on the universal production of carbon-monoxide gas more clear, we have to express the opinion that the enormous and sudden pressure created underground by explosions of mixtures of firedamp and air, or of firedamp and coal-dust, or of air and coal-dust, is sufficient by itself to produce huge volumes of carbon-monoxide gas without the addition of actual flame, and in support of this contention quote the latest estimates of these pressures made by Mr. J. T. Beard, of the International Correspondence Schools, Scranton, Pa., and of Prof. H. M. Payne, of West Virginia University, U.S.A. The former in his recently issued text-book, entitled "Mine Gases and Explosions," estimates the possible pressure at 196 lbs. per square inch, and the latter at from 50 to 146 lbs. per square inch. (Mines and Minerals, February, 1908), and the difference in these estimates arises from the volume of air available, and particularly so in Prof. Payne's estimate, which was based on what he considered did actually occur at Monongah.

The sudden and instantaneous effect of these great pressures on the miners, is to produce loss of consciousness or in some cases death by concussion of the brain, and thus men are found in the precise positions they occupied at the moment of the explosion, or when less severe pressure is produced they are overtaken by the afterdamp before they recover consciousness and are thus poisoned and killed in a few seconds.

Authorities are divided as to whether a small quantity of dust or a dense cloud is the more dangerous, but the author's experience and observation leads them to the conclusion that in the majority of instances it is the dust floating in the air which is dangerous, and, therefore, if more than this comparatively small quantity is present there is then an insufficient volume of air to complete the combustion, and the flame is smothered out. Experience and observation also lead them to conclude that dust is more dangerous in a damp atmosphere than in a dry one, and that there are numerous cases on record where a mine has been described as dry and dusty whereas the air was either saturated with moisture or so nearly saturated that no more than one grain of water vapour per cubic foot would have completed the saturation.

Writers and experts on coal-dust phenomena are generally in accord in treating coal-dust as a very small solid, but the authors of this paper think that it ought not to be treated as solid but as a concretion of gases, because Prof. Bedseh, D.Sc., of the Armstrong College, Newcastle-on-Tyne, has proved by experiments, extending over many years, that every particle of coal-dust freshly produced from the coal face, contains both firedamp and other gases of the paraffin series under pressure, and that these are continuously giving off until the supply is exhausted, and that they are then replaced by oxygen from the atmosphere and not by air, as the atoms of nitrogen are too large to pass through the pores, and are, therefore, filtered out. Consequently it will be readily understood that freshly produced coal-dust being surrounded by the gases escaping from the store occluded in its own small body, floats, as it were, in its own balloon of gas, and is, therefore, immune from any dampness in the air current or, in fact, from any form of water. In many instances the expert evidence given to ascertain the initiatory cause of an explosion is evenly divided between coal-dust only or firedamp only, being the agency by which the original cause, generally a flame from a shot, was extended some distance into or throughout a colliery, and the authors submit that no enquiry of this class can in any case be complete, unless the dust has been examined by what they may term the "Bedson process," and that such an ex-

vestigation would be still more complete if the structure of the dust were examined under the microscope, as was done by Mr. W. E. Garforth after the explosion at Altofts, in England, several years ago (see the report of the Royal Commission on Explosions from Coal-Dust). Taking these two sets of experiments (both due to private initiative and not to the application of public funds) into plain matter of fact consideration the authors conceive that it has been proved by Mr. Garforth without the possibility of dissent that coal-dust is not a solid but is possessed of pores, and by Prof. Bedson that gases exist in these pores under considerable pressure, and, therefore, that every particle of freshly-produced coal-dust ought to be practically considered as a "gas" and not as a solid. As a gas bag surrounded by air it is in its most favorable condition and position to inflame, and explode, and thus to initiate or extend the effect of any flame which is of sufficient intensity to ignite it.

This course of argument and practical demonstration naturally leads up to another of their conclusions on the use of explosives, viz., that it is not possible to use any known explosive with absolute safety in a gaseous mine.

There is, however, another danger which is probably never taken into account, viz., that due to detonation. Every high or so-called flameless explosive requires the application of a detonator, and if the detonator is not sufficiently strong, ignition and not detonation is the result. But assuming that the detonation is complete and that it is an over-weighed shot, we have then to contend with results, which are, in some senses, more dangerous than a blown out powder shot, because we have created a huge detonating vibration which is unaffected by any amount of watering, and which may be communicated to the most distant corners of a mine without demonstrating any effects en route. Supposing, therefore, that either large or small accumulations of firedamp mixed with air exist in any part of a mine, these may be simultaneously exploded by this detonating effect. The Wattstown explosion in South Wales was probably an instance of this effect.

The question which naturally seems to follow this line of thought is, "What percentage of firedamp is permissible in a mine or place where explosives are used?" and this is not so easily answered, because experiments have already demonstrated that less than one per cent. may be dangerous. If, then, one per cent. of firedamp will make a mine dangerous, it would appear rather absurd to blast excepting in such cases where it is absolutely necessary, and then only under the most stringent precautions, but the absurdity of the position is increased when we find that the usual tests for firedamp are made with safety lamps which are incapable of discovering less than two per cent., and on this showing the mine is certified as clear from gas and safe for shots to be fired. The only possible safeguard which the authors have to suggest to add to the safety of gaseous mines when explosives are used, is to limit the weight of the explosive in each shot—that is to say, a large number of small shots might be safe where the same weight of explosive in one shot might cause a disaster—for the valuable discovery, "the charge limit," the writers believe we are mainly indebted to French engineers. The conclusion of the writers is that not more than one per cent. of firedamp is permissible, and that the weight of explosive per shot hole should be limited.

As to whether it is possible to render a coal mine safe against the initiation or extension of an explosion by any application of water, the writers are of opinion that it is positively impossible to restrain the extension of an explosion by any known means of applying water, and, further, that any form of water to dampen the air assists in the extension of an explosion, because as proved by Prof. H. B. Dixon the maximum explosive effect of mixtures of gas and air is only obtained when the atmosphere contains five per cent. of water vapour, and as this percentage can only be attained by the use of steam it is, therefore, an impossible application, and the writers say positively that there is no known means of applying water so as to control the extension of an explosion.

The difficulty of applying water does not, however, end here, because the weight of water which will saturate an air current may vary from, say, 4 to 13 grains per cubic foot, and, therefore, either 4 or 13 grains ought to be equally effective in controlling the extension of an explosion, but this propostion is absurd when we have already proved that five per cent. of the weight of the air and gas mixture is required to give the maximum explosive effect—that is to say, not less than 25 grains per cubic foot of the mixture.

Possibly resulting from the escape of the occluded gases from the coal-dust, it has been found to be extremely difficult to dampen fresh coal-dust, and a practical demonstration of this fact was given to the jurymen at the Monongah inquest by putting about a pound of fine dust into a basin of water, and after stirring it up, and pouring off the water, blowing into the dust when it immediately flew about the court room like soot.

The possibility of rendering a deep, dry and dusty mine proof against the extension of an explosion by water saturation has, however, another barrier against its adoption, and investigation has demonstrated in the mast positive manner possible, that if miners are to work in such mines with any degree of comfort or efficiency the air must be kept as dry as possible, so that the perspiration from their bodies can pass into the air and afford a sense of coolness, for if it does not, then the body temperature rises until what is now described as "heat apoplexy" results, with loss of muscular power, and the man dies. In many deep mines the heat ranges from 75 to 90 degrees Fahr, and, therefore, if the air were saturated with water (9.4 to 14.8 grains) the miners could not possibly work. About 8 grains of water vapour per cubic foot of air should be the maximum dampness permissible in the air of a deep mine.

Another phase of the coal dust problem still remains to be considered, viz., the explosion of dust in mines where firedamp has never been discovered, such as Camerton and Timsbury, in the Somersetshire Coalfield, in England, and so far no experiments have been made to ascertain if any or what gases are occluded in such coal-dust, and as these explosions have originated in old roads, it is possible that the dust had become altered by exposure to the air current, and having absorbed oxygen had become more susceptible to the influence of flame. Only by submitting such dusts to courses of experimental research similar to those already referred to can its ignition or explosion, when exposed to a flame of great intensity, be satisfactorily explained.

The possible speed of a coal-dust explosion has frequently been debated, but without reliable data on which to base an opinion, until the Monongah disaster, when the difference of time between the explosion reaching the surface outside of No. 8 and No. 6 mines

respectively, was observed to be five seconds, and one of the writers has calculated that this would give a speed of 3,000 feet per second. This fact is particularly interesting because it quite upsets those theories which require a considerable time to produce a series of explosions which are not instanteous, and do not take into account the effect of cooling or condensation.

The writers trust that these few notes on a subject which has such a wide range of interest may be sufficient to provoke very considerable discussion and result in the gathering together of much very valuable information, and also produce suggestions for some better and more effective means of exorcising the demon of coal-dust than the present-day ineffective systems of watering.

Note.—Messrs. J. B. and W. N. Atkinson, E. Bainbridge, W. E. Garforth and W. Galloway made an estimate of the velocity of the explosion at Altofts, based on the movement of materials, and this was placed at 99 to 100 miles.—Coal-Dust Report, Q. 3821.

If per minute this would be 7920-8799 feet per second, or more than the speed at Monogah, but if per hour this would only be 132-147 feet per second.

FROM OCEAN TO OCEAN—CANADIAN MINING INSTITUTE EXCURSION.

(By an Occasional Contributor.)

The excursion of the Institute for 1908 covered a larger mineral field than has ever before been visited, on a single excursion, by any party of men. The party gathered at Quebec City on August 24th, and proceeded to Sydney, Cape Breton; thence they gradually worked eastward, visiting the chief and more accessible mining camps in the various provinces, the last mines visited being those of Nanaimo, Vancouver Island, B.C.

There was a two-fold object in organizing this excursion. The Council of the Institute felt that it would be well for its representatives to visit various parts of the Dominion in order to become acquainted with local conditions, and to meet the men of the different camps at home. This part of the work of the excursion was successfully accomplished. The excursionists were splendidly received in the various centres, and they had the opportunity not only of becoming acquainted with the majority of the leading mining men of the Dominion, but they also met many of the chief public men of the various provinces. The excursion has thus made the Institute much better known, and it is felt that the work of the Institute will henceforth be more widely appreciated.

The second object of the excursion was to show the mineral resources of Canada to a number of guests from Great Britain and abroad. Among the societies that sent representatives on the excursion was the Institute of Mining and Metallurgy, London, which sent one of its past presidents, together with its secretary and two members of the Council. Then the British Iron and Steel Institute, the Institution of Mining Engineers, the Mining Institute of Scotland, the South Wales Institute of Engineers, and the Manchester Geological and Mining Society were also represented by well-known members. Among the foreign representatives were the chief geologist of the Prussian Geological Survey, a representative of "Stahl und Eisen," one of the Counselors of Mines of the German Government, and others. The United States was represented by a metallurgist from Columbia University and the Professor of Economic Geology of Cornell University. It may also be added that the party was fortunate in being accompanied by the Geographer of the Dominion and by the Dean of Forestry of the University of Toronto, and by other men who were important factors in making the excursion a success. It is doubtful if another party could be got together that possessed so many elements for success. We even had our own piper. The conductor of the sleepers pleased the Scotchmen of the party and others greatly by his playing. He led us to the nightly frays and brought us home after the slaughter!

The visit of the British and foreign guests of the Institute cannot fail to have an important bearing on the future of the mining industry in Canada. These men will each serve as a centre of information. It will thus be more difficult to misrepresent the industry abroad either by overpraising it on the one hand or decrying it on the other.

Everything contributed to make the excursion a success. As already said, the personnel of the party was right—it possessed the right elements. The presence of the guests of the party pleased the mining men at the various places visited, and made the excursion a greater success than if the party had been composed of Canadians only. During the six weeks of the trip the weather could not have been better. The arrangements of the party were not interfered with by rain at any point from ocean to ocean.

Too much credit cannot be given the railways for what they did to make the excursion a success. During the greater part of the eastern trip the Intercolonial was used, and its service was perfect. From Montreal west by far the greater part of the travelling was done over the Canadian Pacific, and satisfaction was expressed by members of the party for the service that this great railway afforded.

Quebec City.

The party gathered at Quebec on August 24th. They were given a kindly reception and a pleasant send-off at an informal meeting in the Chateau Frontenac by Sir Lomer Gouin, the Premier of the Province; Sir George Garneau, the Mayor of the city, and by the Hon. Mr. Devlin, Minister of Mines. While in the city the party were shown the new historic bridge and other points of interest which attract visitors from all parts of the world to the old city.

Sydney.

The arrangements in Nova Scotia for the entertainment of the members of the Institute and their guests were in charge of the Mining Society of Nova Scotia,

which had gathered in force at Sydney. The evening before our arrival members of the Nova Scotia Society, accompanied by Lieutenant-Governor Fraser, Premier Murray and Minister of Mines Chisholm, had come to Sydney. These gentlemen spent three days with us, and accompanied us on our visits to the Dominion Coal Company, to the Dominion Iron and Steel Company and to the mines and plant of the Nova Scotia Steel Company. Mr. Charles Fergie, the past president of the Institute, and other local men, had looked after the arrangements thoroughly, and the visiting members of the Institute were much pleased with what had been done in their behalf. At each plant visited a good opportunity was afforded of gaining a knowledge of the operations, and the excursionists were much impressed with the size of the coal field and by the scale on which the iron and steel industry is being carried on in Cape Breton.

Various entertainments were provided at Sydney. Luncheon was furnished to the party on each day of the stay by the three companies whose plants we visited. On one of the evenings a smoker was given, and one night was spent in a banquet at the hotel. It is not necessary to say more than that the banquet, smoker and luncheons passed off with the great success usual to such mining functions when held in Nova Scotia. After leaving the plant of the Nova Scotia Steel Company at North Sydney on the last day of the stay the party were the guests of Mr. James Ross on his yacht "Sheila," from North Sydney to Sydney, landing at the residence of Mr. J. K. L. Ross, where a garden party, of which the hosts were Mr. and Mrs. Ross, was attended by the excursionists and by representative people of Sydney. It is thus seen that there was considerable variety of entertainments at Sydney. They all tended to make our visit to Cape Breton a very pleasant one.

Quebec Province.

Leaving Sydney, the party proceeded directly to Levis, arriving early on Sunday morning. The day was spent by many of the party at the Chateau Frontenac. In the evening the Quebec Central train was taken for Thetford Mines, where the party was met by Mr. George R. Smith, past president of the Institute. We were shown over the mines and mill, which are under Mr. Smith's management, and also visited some of the adjoining properties. Leaving Thetford, the party proceeded a few miles to Black Lake, where they were met by Mr. Hopper, a member of the Council of the Institute, and by other representative mining men of the district. Several of the mines and plants in the vicinity of Black Lake were visited. Probably no mineral

C. M. I. EXCURSION AT FERNIE, B.C.

Building is office of Crow's Nest Pass Coal Company, one of the very few structures that escaped destruction by fire.

industry visited by the excursionists impressed them more than did that of the asbestos mines of Thetford and Black Lake. Few of the members of the party previously realized that the industry had reached such great dimensions and that it was still growing so rapidly.

Leaving Black Lake, the party proceeded to Colraine, where they visited the unique and interesting chrome iron ore deposits. Thence they proceeded to Sherbrooke, where they arrived in the evening, and left by an early morning train for Montreal.

On this trip through the asbestos and chrome district of Quebec the party was accompanied by the Hon. Charles Devlin, Minister of Mines of Quebec Province, who did much to add to the pleasure of the trip.

Montreal.

In the evening of the day of arrival in Montreal a banquet was tendered the excursionists by the Montreal branch of the Institute. The Montreal members are to be congratulated on the success of this banquet. The speeches of Hon. Mr. Devlin and others who were on the toast list were of an important character. Mr. Devlin assured the members of the Institute that he had been so impressed with the character of the work which the Institute was doing that he would recommend to the Quebec Legislature that an annual grant be given to the Institute. Moreover, he had decided to send his Superintendent of Mines through with the party to British Columbia in order that Quebec Province might benefit from advice tendered by members of the party concerning the development of mineral resources.

The following day was also spent in Montreal, the visitors being shown around the city by the local members, and being entertained at luncheon at the Hunt Club.

Toronto and Niagara.

On the morning of September 3rd the excursionists arrived in Toronto and took the boat soon after their arrival for Niagara Falls. Mr. P. W. Ellis, one of the commissioners of the Niagara Falls Park, had kindly made arrangements for the entertainment of the party on this side trip. The party had not only the opportunity of viewing the Falls and river scenery, but they were shown through some of the large power plants, and were well entertained through the care which Mr. Ellis had taken in making arrangements for the visit. A number of the local members of the Institute accompanied the party on this visit to Niagara, and assisted in entertaining them during the trip. On the morning of the 4th the party arrived in Toronto. During the day they were the guests of the Exhibition Directors, and had the opportunity of viewing the exhibits of minerals from the various provinces which were shown at this year's Fair. The reception by the Exhibition Directors took on the form of a Government reception, as the acting Premier, Hon. Mr. Foy; the Minister of Mines, Hon. Mr. Cochrane, and the Provincial Treasurer, Hon. Col. Matheson, were present and met the mining men.

Cobalt.

On the evening of the 4th the party left Toronto by special train over the Grand Trunk Railway for Cobalt. They were met at Temagami by Mr. Cole, chairman of the Cobalt branch of the Institute, and by Mr. Black, superintendent of the Temiskaming and Northern Ontario Railway. While at Cobalt and vicinity the party was in charge of Mr. Cole and members of the local branch, Mr. Black looking after the railway arrangements. The arrangements for the entertainment of the guests at Cobalt were perfect. Arriving at the station, Mr. Cole and the committee divided the party into several groups and arranged for their visits to various mines. It was somewhat unfortunate, however, that the party did not have more time in this camp. On the evening of the 5th, owing to smoke on Lake Temiskaming, it was found impossible to take the boat trip which had been planned from New Liskeard. During the evening the members of the party were met at Haileybury station by the founder of the town, Mr. C. C. Farr, and were escorted to the club, where Colonel Hay and other mining men had arranged a pleasant smoker.

Needless to say, the visitors were impressed with what they saw at Cobalt, and with their reception there. The souvenir pins presented by the local committee and the rich specimens of ore so freely given by the mines will keep the camp green in their memories. Cobalt can always be depended on to do the right thing, and always keeps open house.

Temagami.

On Sunday morning, the 6th, the party left Haileybury for Temagami, the Cobalt local committee having arranged for an excursion up the lake. Luncheon was served at the Temagami Inn, and the party returned to the train at Temagami station in the evening.

Moose Mountain.

On the morning of the 7th the party left Sudbury, accompanied by Mr. Hawkes, of the Canadian Northern Railway, and Mr. Leach, superintendent of Moose Mountain mine, for a visit to that property. A number of the citizens of Sudbury accompanied the party, and a very pleasant day was spent on the new railway line between Sudbury and Moose Mountain. This was the only working iron mine which the party had an opportunity of visiting during the trip. The visit was of interest to the excursionists owing to the fact that the deposit is somewhat characteristic of those which are of such great importance in the Lake Superior region.

Copper Cliff.

On the morning of the 8th the party were taken in charge by the Canadian Copper Company. Mr. Turner, president of the company, had made arrangements for the party to visit the splendid new smelter at Copper Cliff and the Krean Hill mine. The gentlemen associated with Mr. Turner were the mine manager of the company, Captain Lawson, and the metallurgist, Mr. Browne. The visit to the smelter, owing to its being so recently constructed and so up-to-date in all its parts, was especially interesting to the metallurgists of the party. Mr. Browne was congratulated on the plant which is directly under his charge. The Crean Hill mine also proved very interesting. Luncheon was given the party at Crean Hill by the company, and proved a pleasant function. It was what may be called the only camp dinner which the party had during the trip, and to many of them it was unique. The Hon. Frank Cochrane, Minister of Mines, who accompanied the party from Toronto to Cobalt and Sudbury, acted as toastmaster at the luncheon, and some highly complimentary things were said of Mr. Turner, his staff and the company which he represents. On returning in the evening from Crean Hill a visit was made to the Victoria Mines smelter, where the party was met by Mr. Corless and his staff. This smelter was of special interest to some of the English visitors owing to their

being acquainted with Mr. Mond and to their having followed the successful career of the Mond Nickel Company. On the return to Sudbury in the evening an informal gathering was held by a few of the excursionists in the King Edward Hotel, where two or three of the guests who had to return east from Sudbury were given a send-off. At Sudbury the party were joined by two or three gentlemen from abroad who had not been able to reach Canada earlier. Leaving Sudbury at midnight, the trip to Winnipeg and the West was begun.

Winnipeg.

Owing to a delay through the burning of a bridge on the railway near Schreiber, the party was not able to spend more than two or three hours in Winnipeg, a city which to the men from abroad was of special interest. They had all read of its rapid growth and present importance. However, they saw enough of the city to convince them that the descriptions they had read were not overdrawn.

At Winnipeg the party was met by Mr. Macpherson, who is in charge of this section of the Canadian Pacific Railway. The party is much indebted to Mr. Macpherson for the care which he took in making the trip westward go so smoothly. He sent his assistant, Mr. Dawson, with the party from Winnipeg, and at various points the party was joined by local representatives of the railway.

Medicine Hat.

The next point of mineral interest visited by the party was Medicine Hat. The trip over the prairie from Winnipeg westward was, however, greatly enjoyed. It seemed a new world. Many of the members of the party decided from the little they saw of the great wheat-raising provinces that Western Canada is indeed destined to become the granary of the Empire.

At Medicine Hat the party was met by the civic representatives of the town and by members of the Board of Trade. Medicine Hat's mineral industry, as is well known, is that of natural gas. They probably make more varied uses of this substance at Medicine Hat than is made of it in any other part of the world. They use it not only for domestic purposes, lighting and heating, but also in the boilers and forges of the Canadian Pacific Railway shops. They are now charging the cars with natural gas, and it is said that the supply of this gas on a car, when it is properly charged, will last longer than will the artificial gases that are ordinarily used for the purpose. Moreover, small pipes are strung along the rails of the track, and the gas is used for keeping locomotives warm when they are standing on the track waiting for orders during the winter. The party was given the opportunity of seeing these various uses which are made of natural gas, and they were also shown the methods by which the flow and pressure are measured.

The people of Medicine Hat are certainly enthusiastic concerning their town. Since the recent visit of Rudyard Kipling they are probably, to use a colloquialism, more "chesty" than ever. On the front page of some of the literature with which they supplied us they have Kipling's saying, as applied to their town, "The town that was born lucky." Moreover, Kipling seems to have been impressed with the immense store of natural gas which has been tapped in the town, and one would think that he favors the inorganic origin of gas as opposed to the organic, since he is quoted as saying, according to the literature supplied by the town, that "This district seems to have all hell for a basement." Mr. Coste, who, as we all know, has been a strong contender for the inorganic origin of gas, has apparently made a distinguished convert in Kipling.

A few miles out of Medicine Hat, at Dunmore Junction, Mr. Coste had arranged to show the party the gas well which had been drilled under his direction a short time before. After showing how the pressure was read and the flow of gas determined, the well was allowed to blow off, and was finally ignited.

Lethbridge.

According to the programme, the party was to visit Lethbridge and other mining camps along the Crow's Nest branch of the railway before coming to Fernie. Owing to the delay at Schreiber it was found necessary to alter the programme and to visit only two or three mines. Hence Lethbridge and some other important mining camps were passed by. At Lethbridge the Hon. Mr. Cushing, Minister of Public Works, Alberta, joined the party and spent the following day with it.

The great landslide at Frank was visited, and at Coleman the party met Mr. Whitesides, who had done so much in making arrangements for the visits to the coal district along the Crow's Nest Railway. A short visit was made to the mine at Coleman and to the newly erected plant at Hosmer.

Fernie.

Mr. G. G. S. Lindsey, president of the Crow's Nest Pass Coal Company, and Mr. R. W. Brock, acting director of the Dominion Geological Survey, joined the party at Winnipeg and accompanied it throughout the trip to Alberta and British Columbia. It is needless to say that both these gentlemen did much to make the trip a success. Having had Mr. Lindsey with us for a few days, we felt perfectly at home on arriving at Fernie, the headquarters of his company. A visit was made to Coal Creek and the mines there. Members of the party expressed themselves as being much impressed with the great coal deposits of this company. The staff took much pains in showing the excursionists through the mines and over the surface plant.

Although Fernie, a town of about 5,000 people, had been practically wiped out by fire a few weeks before our visit, the members of the party were surprised to see what had been done towards rebuilding in the interval. Building was going on not only during the daytime, but the hammers could be heard far into the night. The rapid rebuilding of the town greatly interested the visitors. They here saw something of the pluck, determination, and enthusiasm of the Western people.

Among the few buildings that escaped the great conflagration were the general offices of the Crow's Nest Company. Mr. Lindsey and his staff arranged a smoking concert for the party in the offices in the evening. Those who are acquainted with Mr. Lindsey's skill as an entertainer need not be told that this smoker was a great success. Mr. Lindsey not only made use of his staff, but he called on His Worship the Mayor of the town and on the Chief of Police. Having the Chief present, he was able to make some members of the party perform who had never shown any signs of possessing a "lighter vein" on the earlier stages of the trip. However, having a piper to lead us, we all succeeded in reaching the cars again some time after midnight.

Moyie.

The party left Fernie in the early hours of the morning, and spent the next forenoon in a visit to the mine

and plant of the St. Eugene mine at Moyie. This is the largest silver-lead mine in Canada, and the visit was much enjoyed. Proceeding from Moyie in the afternoon, the party, after leaving the railway, crossed Kootenay Lake to Nelson, where they were met by representatives of the Board of Trade and other gentlemen, who promised them a good time when they re-visited the town in a few days.

Bonnington Falls.

Leaving Nelson in the evening, the party made a night visit to Bonnington Falls, where power for several large mines and plants is developed. Mr. L. A. Campbell and his staff showed the party through this modern and attractive plant. The company, which is known as the West Kootenay Power and Light Co., Ltd., had prepared a pamphlet, giving an account of their plant, which was of much assistance to the guests on their visit, and now forms an interesting souvenir of the trip.

Trail.

Having to make up time lost on the earlier part of the trip, it was found necessary to visit both Trail and Rossland in the one day. This was unfortunate, as all the members of the party felt that they would like to have put in considerably more time in each place.

We arrived at Trail in the morning, and were met by the staff of the smelter and refining company, who showed us through their very interesting plant. Descriptions of this plant have appeared in the press, and it is not necessary to say more concerning it than that it proved to be one of the most interesting places visited during the whole trip. The electrolytic lead refining attracted much attention.

Rossland.

Leaving Trail, the party proceeded to Rossland, where they were met by the local committee, and were entertained at luncheon, afterwards visiting the various mines of the camp. The stay in Rossland was, of course, all too brief, but the party were shown some of the typical stopes and some of the deeper levels of the mines, and were gratified to see how promising the industry is at the present time. Between the visit to the mines and the banquet in the evening, the members were entertained at the attractive Rossland Club.

The banquet, which was presided over by Mr. A. J. McMillan, was a decided success.

The "Rossland Miner" of September 19th gives a full account of the visit of the Institute to Rossland, and is one of the most interesting newspaper issues concerning the excursion which was published during the trip.

Greenwood.

After the banquet at Rossland the party proceeded to Trail, and left for Greenwood, arriving there in the forenoon. They were met by Mr. Keffer, who was president of the Institute last year; Mr. McAllister, and other representative men of the district. A visit was then made to the British Columbia Copper Company's mine and smelter. This mine is of a different type than any we had seen on the trip, and it was a surprise, to some of the party at least, to see what was being done with ore of this grade. The ore body has been systematically blocked out and sampled. So far as the mining is concerned, there is no guesswork about the operations. The same may be said of the smelter. The party were interested in seeing how few men it took to operate this smelter.

As explained by Mr. Keffer and Mr. McAllister, the success of the operations of the British Columbia Copper Company depends on several factors. Firstly, the large size of the ore body; secondly, its uniform grade; thirdly, its being self-fluxing; fourthly, little or no timber being required in mining.

In the evening a smoker was held in Greenwood. This had its special features, but it is not our intention to go into details concerning any affair of this kind.

Phoenix and Grand Forks.

Leaving Greenwood, the party proceeded to Phoenix, where are situated the mine of the Granby company. At Nelson we had been joined by Mr. B. W. Hodges, the general manager of the Granby company. Mr. Hodges is the very active chairman of the British Columbia branch of the Institute, and had given considerable time to organizing the trip in British Columbia. At Phoenix he and his staff showed us over the extensive works and plant of the mine. Some idea of the size of the works can be gathered when it is said that 20,000,000 tons of ore are blocked out. This ore, like that of the British Columbia Company at Greenwood, is self-fluxing. After luncheon, provided by the company at Phoenix, the party left for Grand Forks to visit the Granby smelter. They were there met by the Mayor and other officials of the town, and given a hearty welcome to the town. It may be added that Grand Forks does not depend on the mineral industry alone, but that the surrounding district supports a very prosperous fruit industry. The Mayor and the gentlemen accompanying him made our welcome concrete by presenting us with some baskets and boxes of beautiful fruit of the district, together with several bouquets of their flowers to be used on our dining car.

The smelter at Grand Forks handles about 3,500 tons of ore a day, and it is said that in the not distant future 5,000 tons will be treated.

In the last volume of the transactions of the Institute an account of some of the operations of the Granby company is given. The paper which Mr. Hodges read during our visit to Victoria gives further details.

Nelson.

Leaving Grand Forks in the evening, the party proceeded to Nelson, where they were met by the local committee, of which Mr. Leslie Hill was chairman, and Mr. Beeston, secretary. As the members of the party had been somewhat strenuously at work since their arrival in British Columbia, the Nelson local committee thoughtfully decided to give them a day of rest. They had arranged to take the party on a trip up the beautiful Kootenay Lake, where we got glimpses of glaciers, views of fruit orchards and mineral springs, and at one point where we stopped some members of the party deserted us to enjoy themselves fishing for a few hours. Luncheon was served on the boat, and afterwards a call was made at the Blue Bell mine, where we were received by Mr. S. S. Fowler, who was president of the Institute some years ago. The Blue Bell mine is a type of ore body new to some of us. Its development and the treatment of its ore by Mr. Fowler will be followed with interest by many of the party. On the return trip to Nelson dinner was served on the boat. In fact, it may be called a banquet. Everyone was surprised at the successful way in which this large dinner was carried out on board the steamer. It is only necessary, however, to say in explanation that the service was under the direction of C. P. R. officials.

After dinner on the boat, Mr. Hodges showed that he

could do something more than run the largest metal mine in Canada and organize excursions. He showed that he had musical qualifications. He took charge of the piano, and, others assisting him, a successful musicale was given.

On arriving at Nelson about 9 o'clock it was found that our train would not leave till about midnight. The party was therefore invited to the Nelson Club to spend the intervening hours. It would not be well to describe in detail what happened at the club. Some members of the party might not be let go away from home again alone. One feature, however, of the entertainment at the club will be long remembered. It might be called the union of nationalities, six men, representing different nations, standing together on what we shall speak of as an elevated platform, and one after the other making a speech characteristic of his country. The performance with the interpreter was especially good.

Revelstoke.

The party left Nelson and proceeded to the Arrow lakes, where boat was taken to Arrowhead, our cars having been ferried across ahead of us. From Arrowhead we proceeded to Revelstoke. The scenery on both the lake and in the vicinity of Revelstoke proved very attractive to most of the party, as did also the trip through the Fraser Canyon and on to Vancouver.

Victoria.

We left Vancouver by steamer in the forenoon for Victoria, where it was intended that we should have a restful time for two or three days. After dinner, at the hotel, the Mayor of Victoria welcomed the members of the excursion party to his city. Next morning a meeting of the western branch of the Institute was held in the Parliament Buildings. Mr. Hodges presided at this meeting, and the excursionists were welcomed by Premier McBride, who is also Minister of Mines for British Columbia, and by the Hon. William Templeman, Minister of Mines of the Dominion, whose home city is Victoria.

After these addresses of welcome, papers were read by Mr. Sutton on "The Geology of Vancouver Island," by Mr. Hodges, on "The Granby Mines," and by Mr. Ashworth, on "Coal Dust." All these papers proved to be of live interest.

During the rest of our stay in Victoria several entertainments were provided, the Lieutenant-Governor inviting the excursionists to a garden party at Government House, and a reception was held by the Premier and representatives of the Government in the Parliament Buildings on one of the evenings. The members of the party were also the guests of the Victoria Exhibition Directors.

Most of us had heard that Victoria is a very attractive city, and we were not disappointed in our visit to it. One thing that strikes the visitor is the extensive grounds with the beautiful trees which surround so many of the residences. One might say that

"Here lawns extend that scorn Arcadian pride."

Nanaimo.

On the morning of September 24th the party took train from Victoria for Nanaimo. This proved an attractive trip through the island. We stopped for a short visit at the plant of the Tyee Copper Company smelter, at Ladysmith, where we saw the unloading of ore from some of the northern islands. Being so well situated as regards water transportation, this smelter should get a varied supply of ore from the deposits which are known to occur on the coast of British Columbia.

Arriving at Nanaimo, we were received by members of the city corporation and others and entertained at luncheon. In the afternoon the party was taken in carriages to the collieries of the Western Fuel Company. A number of the members of the party went underground and spent some time in viewing the works. After leaving the collieries the party was taken on a visit to the Hamilton Powder Company's extensive plant, which proved to be an interesting and novel visit.

In the evening the party were the guests of the people of Nanaimo at a dinner, at which the Mayor presided. Altogether, our trip to Nanaimo was a very pleasant and instructive one.

During our stay on Vancouver Island Mr. E. Jacobs, secretary of the western branch of the Institute, did much to smooth our way and make the trip a success.

Vancouver.

We took steamer at 7 o'clock in the morning from Nanaimo for Vancouver. On arriving at Vancouver we were met by the local committee and were taken in automobiles through the beautiful Stanley Park and around the city.

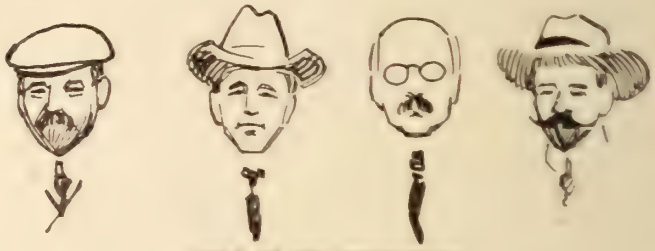
The City Council, Board of Trade and Stock Exchange had arranged for our entertainment in Vancouver. The local members of the Institute had been very active in furthering arrangements, and it can be said that the luncheon in the Vancouver Hotel was one of the most succesfsul functions of the trip. Mayor Bethune presided, and addresses were made by the Hon. Carter-Cotton, Mr. Waghorn, and others. The vsitors were loud in their praise of Vancouver city. It has had a more rapid growth than almost any city in Canada, and now presents a most substantial appearance. Nature has done a great deal for the city. It has splendid harbor facilities, probably the purest water supply of any city of its size in Canada, and a most magnificent park.

The Return Journey.

The party left Vancouver in the afternoon on the return trip, the cars having been cleaned and re-stocked during our visit to Vancouver Island. At Revelstoke Mr. Lindsey and two or three other members of the party left us, they going via Nelson to Fernie. The trip through the mountains eastward could not have been more pleasant. The weather was clear and fine, and the glaciers and other natural beauties of this famous region showed at their best.

Nor was a sight of big game lacking on this trip through the mountains. Members of the party are not quite certain, even now, whether the bears which Mr. Brock pointed out to them at the foot of a slide were tame ones or not. He had been telling some members of the party what they thought were pretty tall bear stories, and he had told them that he would show them some bears along the route. Sure enough, a short distance west of Glacier he pointed to a black specimen and a brown one at no great distance from the track. The brown one seemed to be almost too unconcerned to be in his native state. Some of us suspected that Mr. Brock had got one of his friends to let his tame bears loose for our bentfit—and for his reputation!

Calgary.

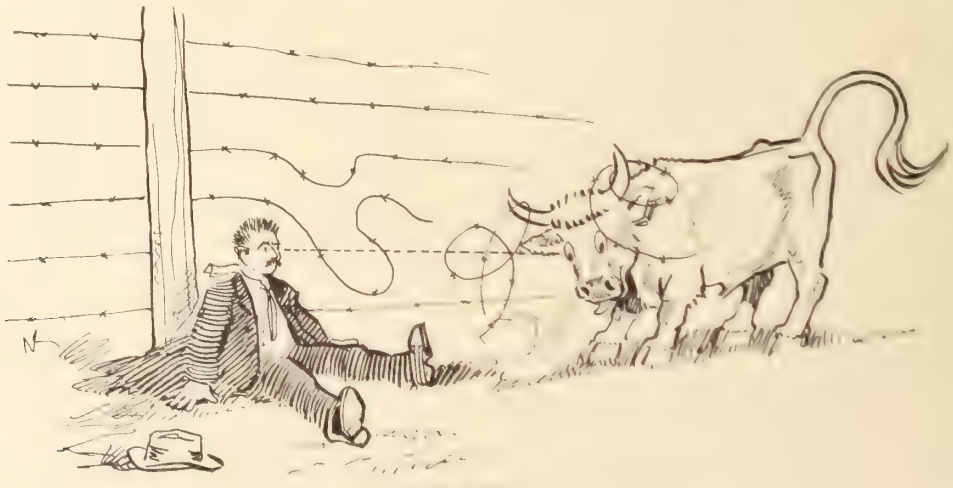


During the visit to Nelson the members of our party had met Mr. P. Burns. There must have been some kindred spirits in the party—that is, kindred to Mr. Burns—as we there and then received an invitation to visit his ranch at Calgary on our trip east.

ST. SIMEON OF CALGARY.

On our arriving at this progressive and rapidly growing city we were met by Mr. Burns and other men of the city and were escorted in automobiles to Mr. Burns' stock yards, where an exhibition was first given of broncho-busting. Mr. Burns had had his men collect some of the worst outlaw horses in the district. He had also invited some of the champion riders of the country to be present, and the exhibition that was given was certainly true to life, to say the least. We all feel that we have seen some of the best riders and the best buckers of the West.

But while the broncho-busting part of Mr. Burns' entertainment was good, the second part, the cattle-taming exhibition, was even better. In an enclosure with a barbed wire fence six strands high, facing the open prairie, Mr. Burns' men had collected some of the wildest and best-running steers in the territory. When the party had gathered at the side of the enclosure these steers were led out one or two at a time, and the horesmen showed their skill in roping them. All went well until about the sixth steer had been given his chance of getting away on the prairie. This animal was one of the wide-horned Texan variety. He ran out on the prairie for three or four hundred yards, and was finally roped by a rider. The saddle-girth broke, and the rider was unhorsed. In the mix-up the steer lost his bearings, and appeared to the crowd to charge the



SOME OF THE PRINCIPALS.

prostrate rider, who, however, succeeded in rolling out of his way. The steer then came back towards the enclosure and directly towards a group of forty or fifty men who were bunched near the high wire fence. Every man in the party thought the steer was coming straight for him. With tail up and head down, on came the steer,

"Untired, untamed, and worse than wild."

The men meanwhile tried climbing the fence. The Cobalt representative, being used to climbing mine ladders, succeeded in reaching the top of the highest post, and felt secure resting on its top. He sympathized with his fellows as the steer rushed by. Unfortunately,

THE CRISIS.

a few yards beyond the party the steer charged the fence and went straight through it. This charge of the steer shook the Cobalt man off the top of the post, and when he picked himself up he was inside the enclosure facing the steer. All that he had ever read of matadors in the ring flashed through his mind. He made an

heroic effort and succeeded in cowing the animal by mind power. The steer turned away, and the Cobalt man again climbed the post. Other members of the party were not so fortunate. At least fifteen men had bleeding hands, cut by the wire, and many articles of clothing, torn on the fence, had to be discarded. Doubtless Mr. Burns' entertainment will be remembered by the excursionists when many of the mining camps are forgotten. On the way eastward, two or three days after the Calgary visit, one of the members was heard to say,

"It Burns at Calgary."

While on the subject of ranching, it may be added that when we first got into the cattle country on our way west one of the members of the party asked: "Do the cowboys milk the cows?"

Conclusion.

After leaving Calgary the party proceeded directly to Montreal, arriving on October 2nd, where a number of the members from abroad took their ships a day or two after.

In the foregoing account of the trip it has been impossible, owing to lack of space, to say more than a few words on each locality visited. Many of the mines and plants have, however, been described in technical journals, and doubtless a number of papers will be published by members of the excursion. The men from abroad frequentely commented favorably on the literature with which they were furnished on the trip. This literature included geological descriptions and mining data on nearly every locality visited.

COBALT COMMENTS.

ALEX. GRAY.

Scientists Must Decide.—By common censent the Montreal River and its tributaries traverse territory regarded by field geologists as the heir-presumptive or heir-apparent to Cobalt. What the division of the unentailed estate is likely to be only the specialist in prospectus lexicography will attempt to detail. He has already bequeathed putative wealth "surpassing" Cobalt and a "rush," which means to mining investors that they need not "come early" if they would "avoid the rush." Cobalt was the very rare exception where "first come, first served" rewards obtained. Too frequently mining vistas have "dead ends," and before Elk City's suburbs become fashionably residential and industrial, it will be material that the "surpassing" business be carefully managed, "Fly City" being the solitary urban centre where the preposterous spells prosperous. There has been less of the vainglorious about the Montreal River mineralized areas. Early settlers were unsettled by stratigraphic innovations and affected by objurgations directed at Cobalt promoters. They staked "conglomerate," blazed their way around quartzite, uncovered what they could for "discovery" purposes, and "snowshoed" what they could not find. Blizzards and "black flies" were not deterrents; yet what violent fluctuations there were in the market for claims had a downward tendency until ciphers began to be lopped off the affixes, and numerals prefixed were modified in inverse ratio. The scientist (and the capitalist behind him) was more omniscient than omnipresent. Too much gas was leaking from Cobalt's balloon and Montreal River claim owners perforce had to resort to the perachute. It has followed that a course in the school of adversity has effected more of reason than of riches, and without traversing the contentions of specialists as to Cobalt's superiority, the undemonstrative scientist has put the intelligent prospector in the middle of the thoroughfare. Without that scientist the accommodations at Elk City would not have been augmented and "assessment work" would be the limit of development in other than isolated instances. With that scientist there is no "rush," stampede or scrimmage. He has not been entirely satisfied with the fissuring in some of the townships; he has been thoroughly dissatisfied with the tactics of those who undertook to make claims-mongering a menace to the mining sciences. Ultimately rationalism has prevailed and there is a likelihood of equitable arrangements by which the party of the first part will not deprive the party of the second part of his hope of future reward and incidentally consign the section to demnition. As a further compromise Gowganda might be the metropolis and re-christened Barlow, leaving it for that scientifically named ste to contest for honors with Miller. In either event there need be no "rush" nor is it advisable to have recurrecnes of such incidents as the following, related in a Renfrew paper:

"At Gowganda Lake slabs weighing 40 pounds are removed without putting in a shot. At that point there are some 1,500 men, with the transportation problem one of the most serious ones confronting them. Every owner of a canoe carries his paddle with him when leaving the water, to guard against the disappearance of his canoe in his absence. What he calls a Marathon race, with a mine as the prize, Mr. Connolly saw during his trip. A dispute arose as to the ownership of a claim and the mining inspector was asked to settle the question. Two men each represented the rival claimants, and upon a decision being arrived at in the recorder's office two canoes moved off at top speed for a new staking of claims. The distance to be travelled was fifty miles. One of the men in the race was a Renfrewite. One couple upon arriving within eighteen miles of the coveted claim set off some dynamite, as a signal to men stationed farther in and these in turn passed the signal along, resulting in a new staking taking place, one of the claimants beating the other by a good margin. Such is life n a mining country."

Is it a coincidence that the signal was pre-arranged? Verb. sap. More of this on the "rush" would make "life in a mining country" an excellent thing to forego.

Economic Cross Purposes at Cobalt.—Events in the north country, apart from trapping and lumbering, had their beginning when those Canadians, McKinley, Darragh, the McMartins, La Rose, Hebert, Trethewey, Longwell and, above all, Miller, discovered and diagnosed cobalt. Gradually this fact has been brought home to Canadian men of affairs, but the dawning has been so unnecessarily prolonged that those who should have been the beneficiaries now must be satisfied with seats at "the second table." It is undoubted that the

business interests of the Dominion were slow to realize the potentialites of Cobalt. They are hardly awake to the accumulating possibilities and probabilities of the districts surrounding Cobalt—districts quickly appealing to alert aliens with affinities for the best there is and more of the same. Probably these sources of profit are as safely conserved in New York as they would have been in the custody of "original owners." They were financed in the States because Canada defaulted. Inevitably the larger and richer areas have gravitated to the pockets of these who really took few risks when they assumed well-guaged certainties, and so five prosperous companies which have paid 53 per cent. of all the dividends from sixteen companies at Cobalt are directed from Broadway, Buffalo and Rochester. These companies have sent away about 60 per cent. of Cobalt's output. Nine of the producing non-dividend companies have New York control. Three are in the crucibles. Perhaps it does not matter so much so long as more mineralized sections are being opened out, but the indifference of dominant forces in Canadian communities to the precious metal contents of the north country will either have to be modified or there should be a surcease from grouching when Americans appropriate "the persimmous."

It is not a matter for off-hand criticism that plums have been plucked by those with the quickest and longest reach. Rather is it a subject for review to be taken as a course in neighborly affection and co-operation without being inhospitable toward visitors with credits at their disposal. Then the equities will be preserved and more of the La Rose net earnings of $3,850 per working day will revert to "the place of issue," more of the Nipissing profits in corresponding degree will remain here, along with the daily proceeds of about $2,500 from the Coniagas; and the Kerr Lake Company's daily contribution of about $2,525 will also be balanced between residents south of the Bronx and those north of the Great Lakes.

What Canada loses by its liberality, notwithstanding the La Rose cannot be said to have involved a sacrifice is displayed in the profit sheet of these standard mines. Not alone have losses in minerals unaccounted for been grievous, and refining costs adverse until within this year, but much of the power of the wealth produced has been directed toward the purchase of more of the mines, until the whole situation becomes such as to warrant at least more than casual comment.

To make it clearer that while millions are being made at Cobalt, millions more could be saved there these figures are offered with the morals they contain:

To mining men these tables represent profits and losses on contained minerals. To Canadian men of affairs they represent incidental trade and about 25 per cent. of the gross value of the products—enough if there was more of it and if the other two or three quarters were restored upon Canadian terms. Instead of this the attitude of Canada has been either passive or repellant toward its mining fields, and its surplus funds are scattered all the way from the Rio Grande to Terra del Fuego, while even the economies essential to the

local treatment of Cobalt's complex ores are in "the other fellow's" balances, vide the foregoing data and this from the annual statement of the managing director of another prosperous mining company, the Kerr Lake:

"The price of silver during the year has fluctuated greatly. Last year we obtained an average of 67¾ cents per ounce for our silver, while this year we have been forced to sell it as low as 51¼ cents. This condition cannot remain for any great length of time, as the metal is now far below the normal price. Under the existing conditions we are producing only sufficient ore for our requirements, which are our quarterly dividend of $90,000 and our working expense and outlay for additions and improvements, averaging about $15,000 per month. The marketing of our product has been a very serious matter, inasmuch as the smelting works were unwilling to buy the very rich ore which we produce, owing to the difficulty of gettng a correct sample by the ordinary means common in the purchase of silver ores. We attempted to cupel, or reduce, the entire amount of our shipments by melting the ore down and taking the resulting silver, but the losses by and the cost of this method we found to be so great that we abandoned it. Experiments at the mine have been undertaken during the year by our engineer, whereby a good deal of the meal is separated from the ore before it is shipped. In July, for instance, 1,000 lbs. of native silver were taken from the ore by the simple process of crushing and screening. By carrying this method a little further we will be enabled to ship ore to the smelters which can be sampled with less difficulty, and marketed, we believe, without the troubles which have been encountered during the past year."

Not only is it in evidence that Nipissing, La Rose and Kerr Lake have been earning large percentages for owners. It also is painfully apparent that silver on the down grade and involved in precarious markets was handicapped by the "undesirables" associated with it in the form of cobalt, niccolite, arsenic. At the Coniagas and O'Brien it is not so. Everywhere else economic minerals associated with the silver have proved to be hardships leaving it for the richer properties to meet their obligations out of the silver. The Nipissing alone throughout has made the subordinate metals a substantially profitable factor. Others have come into line under the leadership of La Rose, O'Brien, Coniagas, Buffalo, Trethewey, McKinley-Darragh, Hudson Bay and Right of Way. Concentration of lower grade ores and "crushing and screening" as prescribed for the Kerr Lake and Nova Scotia, will doubtless alter the complexion of balance sheets; but the Government sampler would materially aid in this if its erection is not to be indefinitely deferred. None of the mines will acquiesce in the metallurgical reprisals of the past. They cannot. Had the La Rose been mined as scientifically as it is under the present administration it would have had more to show for it; and if the Coniagas smelter at Thorold will elaborate the advantages of its imperium in imperio policy from drill bit to refinery, Cobalt will be better able to demand the support so grudgingly granted by all but outside capitalists, and almost denied by Canadian financiers.

Great pressure is used in manufacturing the new shingles of asbestos-fibre and Portland cement, and they absorb only 5 per cent. of their weight of water. Hydration and gradual crystallization on exposure on roofs make them absolutely impermeable.

BEHREND DRY CONCENTRATOR TEST.

Milton L. Hersey Co., Ltd. Montreal, Aug. 8, 1908.

Certificate of Assay.

Sample of Cobalt ore received from Mr. Louis B. Jennings, Corona Hotel, Montreal, marked "Heads, Cobalt Lake Dump": Gold, none; silver, 35.5 ozs. per ton of 2,000 lbs., value per ton $18.81; cobalt, 1.57%; nickel, 3.10%. Silver at 53c per oz.

September 10, 1908.

Sample of ore crushed, received from Mr. Louis B. Jennings, Corona Hotel, Montreal, marked "Concentrates, Cobalt Lake Dump": Silver, 149.1 ozs. per ton, value per ton $76.04; cobalt, 7.06%; nickel, 18.07%. Silver at 51c per oz.

Sample of ore crushed, received from Mr. Louis B. Jennings, Corona Hotel, Montreal, marked "Tails, Cobalt Lake Dump": Silver, 12.0 ozs. per ton, value per ton $6.12; cobalt, 0.17%; nickel, 0.94%. Silver at 51c per oz.

OHIO COAL MINES.

The following act was drafted at the instance of the Ohio miners, and passed by the last session of the Ohio Legislature, becoming a law on the 3rd inst.:—

An Act Governing Power, Other Explosives, and Blasting in Coal Mines.

Be it enacted by the General Assembly of the State of Ohio:—

Section 1. Storing blasting powder or other explosives.—No blasting powder or other explosives shall be stored in any coal mine, and all powder sold to miners by the keg shall be packed in kegs which have an opening at the edge two inches in circumference, and that can be conveniently opened, to avoid the dangerous use of picks to open the same; and no workman shall have at any one time more than one 25-pound keg of black powder in the mine, nor more than three pounds of high explosives; and no explosive shall be taken into or out of any part of the mine in mine cars propelled by electric power; and no person shall keep blasting powder, or explosives, dangerously near the electric wire or power cable in any part of the mine where electric wires are in use.

(a) Boxing and Distance.—Every person who has powder or other explosives in a mine, shall keep it or them in a wooden or metallic box or boxes, securely locked, and said boxes shall be kept at least five feet from the track, and no two powder boxes shall be kept within twenty-five feet of each other, nor shall black powder and high explosives be kept in the same box.

(b) Handling Explosives.—Whenever a workman is about to open a box or keg containing powder or other explosives, and while handling the same, he shall place and keep his lamp at least five feet distant from said explosive and in such position that the air current can not convey sparks to it, and no person shall approach nearer than five feet to any open box containing powder or other explosives with a lighted lamp, lighted pipe or other thing containing fire.

(c) Tamping.—In the process of charging and tamping a hole, whenever in the opinion of the mining department this becomes necessary, the needle used in preparing a blast shall be made of copper, and the

tamping bar shall be tipped with at least five inches of copper. No coal dust nor any material that is inflammable, or that may create a spark, shall be used for tamping, and some soft material must always be placed next to the cartridge or explosive.

(d) Firing Shot.—A miner who is about to fire a shot with a manufactured squib shall not shorten the match, saturate it with mineral oil nor ignite it except at the extreme end; he shall see that all persons are out of danger from the probable effects of such shot, and if it be a rib shot, he shall notify the person or persons working next to him on said rib before said shot, and shall take measures to prevent anyone approaching by shouting "fire" immediately before lighting the fuse; no person shall return to a missed shot until five minutes have elapsed. And when it is necessary to tamp dynamite, nothing but a wooden tamper shall be used.

Section 2. Penalty.—Any person violating any part of this Act shall be deemed guilty of a misdemeanor, and upon conviction be fined, not more than one hundred dollars, nor less than five dollars, at the discretion of the court.

Section 3. This Act shall take effect and be in force six months after passage.

CONDITIONS OF EMPLOYMENT IN NOVA SCOTIA COAL MINES.

Coal mining companies, operating in Nova Scotia, are required to keep in the office at the mine a register, in which are kept the name, age, residence, and date of first employment of all persons employed in connection with the mine. These registers must be produced at the request of any provincial or district inspector, who has the privilege of copying them.

No boy under the age of sixteen is permitted to work below ground, and no boy between the ages of twelve and sixteen years is permitted to work above ground unless he can furnish a certificate from a duly qualified provincial teacher to the effect that he is able to read and write and is familiar with the rules of arithmetic as far as and including division. No woman or girl of any age is permitted to be employed in the workings of any mine.

EXCHANGES.

The South African Mining Journal, September 5, 1908.—An editorial on the outlook for the Rand is cheerfully optimistic. "A silent industrial revolution has been effected in these fields. The inefficiency, waste and extravagance that characterized the early days of every mining field have been swept away. Not only of the Rand, as they characterized the early days has a striking reduction in costs been achieved, but things have been put in trim for a still further reduction." One of the leading mining firms has appointed as its adviser a consulting engineer whose experience has been confined to the organization and operation of Welsh coal mines, "where the saving of a fraction of a penny per ton is a matter of infinite pains and moments." This is taken as a promising sign.

The Mining World, October 10, 1908.—The first of a series of articles on "Some of the Large Stamp Mills of the World" appears in this number of our contemporary. C. C. Christensen is the author. The Alaska Treadwell and the Alaska Mexican mills are the subjects of this installment. In the 300-stamp mill of the Alaska Treadwell Mining Company two series of 150 stamps are arranged back to back. The stamps are grouped in double batteries of five stamps each. Wooden pulleys, 72 inches diameter by 15-inch face, keyed on the outer ends of the cam shaft, receive the power for each set.

The 1,050-lb. stamps are lifted by double cams, and drop 97 times per minute, in order 1, 3, 5, 4, 2, crushing an average in a year's run 5½ tons ore per stamp per 24 hours.

Steel shoes, heads, tappets, and cams are used. Iron dies are made in the company's foundry. One pound of chrome and Koppel steel in the shoes will crush about 3 tons of ore, and one pound of iron in the dies will crush about 4.4 tons.

The Iron and Coal Trades Review, October 9, 1908.—The current number of the Review demonstrates the probability of the development of an English market for French Lorraine iron ores. The export of this ore is a necessary feature at the present stage of France's coal production. France is quite unable to use all of her own iron ore output. Great Britain should be a purchaser in the near future.

The Mexican Mining Journal, October, 1908.—This number of our excellent southern contemporary contains a short paper on cyanide practice at Pachuca. The author, Mr. E. O. Daue, brings out several useful points. Cyanide practice at Pachuca has not become uniform enough to be described as typical of the district. On many points there are still divergences. At the Hacienda Lorato the ore, consisting approximately of 75% quartz, 5% alumina, 5% calcite, with some pyrite and a little pyrolusite, and containing 1.1 kilos silver per metric ton, is crushed to about 1½ inch ring by four 7x10 Blake crushers. In the stamp mill the ore is crushed through a 16-mesh screen in a 0.02 to 0.04 % cyanide solution. The stamp mill consists of twenty 1,050-lb. stamps, dropping 106 per minute. The pulp passes to 8 Wilfley tables, and the taling from these tables to a series of 14 Pachuca chain mills. The mills grind the pulp to 40-mesh, and are supplied with additional coarse ore up to their capacity. The coarse ore prevents sliming, and increases the capacity of the mills. From the mills the pulp passes to a series of cones, the overflow going to a series of Johnston tables and the underflow to another series of the same tables. There are 38 of these tables in all. The tailing is elevated to two Dorr classifiers, where the sand and slime are separated. The slime flows directly to cyanide tanks; the sand is re-ground in three tube mills and returned to the classifiers. The pulp fed to the cyanide plant gave the following results:—

Remaining in 100 mesh...	5.1%	— 607	—3.0
Remaining in 120 mesh...	20.6%	— 641	—3.0
Remaining in 200 mesh...	29.3%	— 718	—3.0
Remaining in 200 mesh...	36.0%	—1.082	—5.5

The theoretical extraction on this plant is 87%.

At the Hacienda, San Francisco, the Brown system of air agitation is in use. Here the extraction is about 90%.

PERSONAL AND GENERAL.

List of members elected at Council meeting, held October 10th, 1908:—

Members—Roger Beck, Swansea, South Wales, Eng.; W. Chas. Carter, care Dominion Iron & Steel Co., Ltd., Sydney, N.S.; Norman R. Fisher, B.Sc., M.E., Cobalt, Ont; H. L. Kerr, 68 Admiral Road, Toronto, Ont.; J. W. Powell, Coleman, Alta.; Dolph Rosewarne, M.E., care Mr. Cecil M. Bryant, Vancouver, B.C.; L. R. Symmes, Giroux Lakes, Ont.

Associates—K. C. Allen, care Le Roi Mining Co., Ltd., Rossland, B.C.; Alex. M. Bilsky, Cobalt, Ont.; Sydney Smith, General Manager Duchess Silver Mining Co., Ltd., Cobalt, Ont.; Milton Steindler, care Kerr Lake Mine, Cobalt, Ont.; Alfred J. Young, North Bay, Ont.

Student—Athur F. Braid, Sewaren, N.J., U.S.A.

The death is announced of Mr. Bennett H. Brough, Secretary of the Iron and Steel Institute. Mr. Brough died on Saturday, October 3rd, at Newcastle-on-Tyne.

Mr. Brough was born 48 years ago. His technical education was gained on the Continent and in England. In 1886 he was appointed instructor in mine surveying at the Royal School of Mines. Seven years later he accepted the secretaryship of the Iron and Steel Institute. Mr. Brough's best known work is his textbook on mine-surveying. This volume, now in its twelfth edition, is widely used. Of his other important contributions to mining literature there is not space for detailed mention. It is sufficient to say that he was a vigorous and well-informed writer. His services were in constant demand, both as a contributor to the press and as an organizer.

INDUSTRIAL PAGE.

WAY'S POCKET SMELTER.

In California there is a company manufacturing a pocket smelter for testing ores, which is proving a success. Way's Pocket Smelter Company, of South Pasadena, California, are marketing this useful outfit, which consists of a small tablet about the size of an ordinary playing domino, one side of which is liberally indented.

In composition it is carbon, subjected to a mechanical treatment which gives it a fluxing and reducing quality, rendering it highly combustible. This tablet furnishes the necessary furnace, heat, and crucible without, apparently, containing either. Tests are made by pulverizing the ore in a small iron mortar, furnished with the outfit. The finely powdered ore is then spread evenly over the tablet, and when a match is applied burns rapidly, leaving a tablet the same shape and size, apparently of charcoal. The ore, however, is reduced, and is in the burned tablet, in a finely divided metallic condition. This burned tablet is then put in the glass mortar, thoroughly ground and "panned." If there is any metal in the rock it will be plainly visible against the dark green glass of the mortar. The smelter will reduce to a metallic state ores containing gold, silver, patinum, copper, tin, lead, bismuth, zinc, etc., and will enable the prospector to quickly determine whether or not any rock carries "values." This simple device will enable one to readily ascertain by reliable test the contents of any rock.

With Way's pocket smelter and a few simple tools in his kit the prospector, or anyone with an observant eye, is completely equipped for the discovery of valuable metals. The complete pocket smelter outfit, ready for use in the field, contains everything necessary (except acid, which can be procured anywhere) for immediate utilization. It contains one box of smelters (30 tests); one iron mortar and pestle (special design); one green glass mortar and pestle; one patented dropping bottle and case; one double lens magnifying glass; one 40-mesh screen; magnet, and complete instructions. This outfit, securely packed, sells for $5.00. A smaller outfit is also put up, which consists of one box of smelters; one patent dropping bottle and case; one iron and one green glass mortar, and complete instructions, for $3.50. With the use of Way's pocket smelter you can accurately determine, on the ground, the metal contents of any ore at a cost of only 5 cents for each test. The manufacturers find that about 75 per cent. of their sales are made to mining companies. Inquiring into the matter, they ascertained that the mining companies make preliminary tests at the mine on ores, and send only those which show values to be assayed. This saves the mining companies considerable money in the course of a year. By writing Way's Pocket Smelter Company, Box 945, South Pasadena, California, you can get a free copy of the "Prospector's Friend," a valuable booklet, which explains in detail the pocket smelter outfit and other valuable information for mining men and prospectors.

Franklin Air Compressors, Catalogue No. 26, Chicago Pneumatic Tool Company, Chicago.—Frank compressors are built in more than one hundred sizes and styles, to suit all purposes from motor hoists to pumping natural gas. In design these compressors follow the most approved steam engine practice, working along original lines only in details vital to economical air compression. The catalogue before us illustrates all essential varieties.

J Edition, Catalogue of W. F. Stanley & Company, Surveying, Engineering, and Mathematical Instruments, 286 High Holborn, London, W.—In this well-prepared catalogue, amongst a complete range of surveying and engineering instruments, illustrations are shown of several complete mine surveying outfits. The Stanley instruments have a world-wide reputation.

Ackroyd & Best's Safety Lamps are described in a recently issued catalogue. Many advantages are claimed for this make of safety lamp. It need not be lighted until it is actually needed. Lighting takes but a few seconds. Underground re-lighters are supplied whereby a lost flame can be replaced quickly and safely. The lamp can be cleaned rapidly, filled expeditiously and cleanly. It can be opened only by means of a powerful electro-magnet.

Messrs. Ackroyd & Best have introduced a Maintenance Contract System, under which they supply

their patent lamps, together with lamp-room igniting and magnetic unlocking apparatus, oil filling machine, one safety underground re-lighter for each 100 lamps, together with oil having flash point of at least 250° as required for working single shifts, wicks, and renewals; for a small weekly sum, payable monthly.

Colorado Iron Works Company, Denver, U.S.A., Catalogue No. 10 B., Cyanide Plants, Machinery, Tanks, and Appliances.—The modern trade catalogue is often quite as instructive and, not seldom, much more interesting than the usual text-book. Catalogue 10 B is one of the best conceived that we have seen in a long time.

The catalogue proper is preceded by a short description of the cyanide process, which is clear, concise, complete, and suitably illustrated. In fact, this preliminary treatise should prove most instructive to anyone interested in gold milling. The catalogue includes ample descriptions of all cyanide plant accessories.

The Hill Clutch Company, Cleveland, Ohio, have published an illustrated catalogue dealing with their collar oiling bearing and the various attachments. Full specifications are included. The Hill Patent Collar Oiling Bearing is so constructed that it will not leak nor will the oil creep along the shaft. There is no waste of oil. It operates for months with one filling.

Wire Ropes.—This is the title of an attractive catalogue issued by **W. B. Brown & Co. (Bankhall), Limited,** whose head office is 63 new Broad Street, London, E.C. W. B. Brown & Co. are manufacturers of steel wire ropes and cables for mining, aerial cableways, tramways, suspension bridges, shipping, and all engineering purposes.

In the construction of their steel ropes W. B. Brown & Co. exercise the most minute care. The material is selected after close inspection. Every wire used is tested for breaking strain, elongation, torsion, and flexion, and a record is kept of the wire retained for manufacture. Regularity and evenness of the material used is thereby ensured. The history of tests performed on each rope is kept on record, and is always open for reference. This makes possible an exact repeat order, and buyers can depend upon getting at any time a repeat rope of exactly the same quality as its predecessor.

The catalogue contains useful information concerning the handling and care of ropes. Full specifications of sizes and grades are given, together with tables for determining the diameter of rope suitable for given loads. Many incidental attachments are illustrated. An ordering telegraph code is appended.

Bulletin No. 1428, received from the Allis-Chalmers Company, Milwaukee, is an article on the Allis-Chalmers hydraulically operated copper converters, reprinted from the Mining and Scientific Press. It describes an installation of two hydraulically operated stands and eight shells, 96 inches by 150 inches long. Each converter of these dimensions, assuming six charges per stand per 24 hours, and 26 working days per month, has a capacity of about 1,250,000 lbs. copper per month. The tuyere arrangement is especially to be commended.

Special Publication No. 7061. Canadian Westinghouse Company, Limited, Hamilton, Ont.—The Baldwin-Westinghouse electric locomotion for mining and industrial traction are here well described. The co-operation of the Baldwin Locomotion Works with the Canadian Westinghouse Company is a guarantee of the best modern locomotion design along with the electrical equipment. Electric haulage is clean and economical. By its use fire risks are removed in working around inflammable material. This catalogue sets forth the subject completely.

Perforated Metal, Bulletin 1425, Allis-Chalmers Company, Montreal.—The Allis-Chalmers people outline in this bulletin a few of their ranges of perforated sheet metal. Mining screens, grizzleys, screen plates, separators for coal, ore, phosphates, etc., are included. Full directions as to ordering are presented on the third page.

The Lea-Degen High-Duty Turbine Pump, Bulletin G, The Lea Equipment Company.—The Lea-Degen high-duty turbine pump is built in separable unite, and is parted both horizontally and vertically. These parts can be assembled rapidly and re-assembled in any desired combination. The trouble of packing is done away with entirely by means of right-angle cup-leathers, held in place by springs in such a manner that they are tight under all conditions. They allow the shaft to oscillate throughout any distance necessary, and are quickly renewable. Another most important point is that both suction and discharge are placed below the centre line of the pump, allowing removal of top without breaking water connections. Bearings are all of a self-oiled type. There are many other points of interest.

The City of Cobalt Mining Co. and the Temiskaming Mining Co., Ltd., have recently ordered air compressors for their properties in the Cobalt district, which represent a considerable step forward in the type of power machinery used in that camp.

These machines are of the Corliss tandem compound steam and two-stage air pattern, manufactured at Chicago by the Sullivan Machinery Company. Most of the air compressors now in service in the Northern Ontario district have been selected with a view to low first cost, since the mines have hitherto been in a stage of exploration, rather than of permanent production. These compressors, while performing well the purpose for which they were designed, have not been of a type economical in power consumption.

Fuel at Cobalt is expensive, owing to the long distance of the district from coal fields, and of the difficulty of hauling it from the railroad to the mines. The two Sullivan compressors just ordered are especially designed to secure a high degree of steam economy at a moderate first cost, with low expense for foundations and house-room.

PRESERVATION OF WIRE ROPE.

Where wire ropes are worked in places where they come in contact with acid water, or in hot and wet shafts, it is found that galvanized wire, of as large gauge is practicable, fills the requirements best. Before the ropes are used they should be coated thoroughly with a suitable lubricant applied hot. Cold lubricants are of little use. In the absence of lubricants the ropes rust out much more rapidly than they would wear out normally.

SPECIAL CORRESPONDENCE

Glace Bay, Oct. 19th, 1908.—The members of the P. W. A., who have left that body and joined the U. M. W. A., think they should have some share of the Defence Fund of the local organization, and they obtained an injunction restraining the Grand Officers of the P. W. A. from acting in that capacity until the claim of the U. M. W. A. faction is decided by the law courts. The case has been tried before Judge Graham at Sydney, who reserved his decision, and granted a continuance of the injunction until his decision is given. Somehow or other a political twist has been given to the internecine warfare between the unionists, and Mr. Justice Graham will very likely reserve his decision until after the election pother has subsided and reason resumes her sway.

The late strike of the C.P.R. employees has been an object lesson in the futility of strikes in Canada when engineered in the States. The sympathy of the Canadian public never will be with any body of workmen who strike at the dictation of international labor unions, and it cannot be gainsaid that public sympathy is the one and only force that will enable any labor union to win a strike. There have been very few strikes that have had less justification than the C. P. R. strike. It was deliberately called at the moment when it was most calculated to disorganize the carrying trade of the Dominion, with an utter disregard of public convenience. In direct consequence of this alienation of public sympathy, we believe, the strike failed in the most abject manner. The same abject failure, it may safely be prophesied, will attend any and every attempt to apply the methods of American trade unionism in Canada.

In our last letter we referred to the supreme importance of the St. Lawrence trade to the coal industry of Cape Breton, and to the very narrow margin by which this market is saved to Canadian operators. The people of Nova Scotia, if their would-be parliamentary representatives and their newspapers are any guide, do not realize these facts. Both political parties seem to be making a dead set at the coal trade. It is surprising how little some people recognize the hand that feeds them, and how lightly they discuss legislation on matters of which they are usually entirely ignorant. The representatives of one party wish to impose upon the coal trade an Eight Hour Bill, similar to that freak of class legislation shortly to occupy the attention of the House of Lords in England. The other party is blethering about Norwegian shipping in Canadian coastal waters, and the alleged extortionate price of coal. The newspapers who excite themselves over these Frankensteins of their own imagination usually refer to the coal operators as "barons." Exactly why nobody knows, but it sounds well, and all these papers have a penchant for a gentleman who was called Munchausen.

As to the selling price of coal. When it is considered that the miners of Cape Breton earn possibly as high wages as are paid to coal miners in any country, where the conditions of living approach the normal, and that coal is sold in Nova Scotia at a cheaper rate than in any European country, we fail to see where the extortion and injustice appear. The coal mines of Cape Breton are distant from Halifax almost twice as far as the mines of Derbyshire are from London, yet coal is cheaper in Halifax than in London.

The extortions of the coal "barons," which, according to the jeremaids of the newspapers, are wrung from the withers of the people, are so large that not a single coal company in Nova Scotia is really paying. The largest of them all, the Dominion Coal Company, has not paid one per cent. on its capital, reckoned from incorporation to date. Another large company has just passed its dividend, and one, at least, of the smaller companies is in the hands of the sheriff. But they have paid by far the largest portion of the provincial revenue, and they have supported at least one-quarter of the whole population of the Province. Even coal companies have their little uses.

The extraordinary attitude of one newspaper is well instanced by its conduct on two different occasions. Three men were killed at a Nova Scotian mine, directly through the negligence of a fellow-workman. This newspaper asked the Attorney-General to take steps to arrest the president of the company for manslaughter before he absconded! Another company, at very considerable expense, equips its mine with the latest appliances for saving life and property, and is able to render valuable assistance to a neighbor. This newspaper studiously avoids any mention of these facts. And this attitude is typical. Anything that can be raked up against the large coal operators is heralded abroad with colored headings, and anything that would tend to show a spark of saving grace is studiously suppressed.

Whole sheets are being written about the woes of schooner captains, whose distresses are stated to be entirely due to the growth of Norwegian shipping. All of this touching editorial solicitude for the poor schooner captain is so much politics. We can pass this phase, for it is evanescent.

What is the truth about Norwegian competition and the schooner trade? First of all, sailing vessels are out of date, and only exist to-day on sufferance. Steamers, large and small, are gradually ousting the schooner. The Norwegian vessels are up to date. These people have captured a large slice of the coastal trade, because they have been sufficiently enterprising and farsighted to build just that particular type of boat that will give the quickest despatch and the lowest freighting costs. The Norwegian is a born sailor, and does not, even in these modern days, belie the Viking's blood. The mate of a Norwegian ship may look like the deckhand of a British tramp steamer, and he certainly works like one, but his conversation is that of an educated gentleman. It is said that the Norwegian sailor lives on food that any proper-minded British citizen would refuse. The writer recently sampled the menu of both an English and a Norwegian ship, and preferred the latter. The whole reason for the growth of Norwegian shipping is that the Norwegian captain knows his business, is a fearless navigator, and his ship is built to suit the trade in which it is to be engaged. All the Norwegian ships that sail Canadian waters were built, not in Norway, but in England. The cantilever patent on which many of them are constructed, is the property of a Tyneside firm. They pay fair dividends to the shareholders in Norway. But we cannot see how the exclusion of Norwegian vessels is going to help the schooner captain. It is a little late in the day to freight coal up the St. Lawrence in schooners, and if the Norwegians go, British bottoms will replace them. There are no Canadian ships capable of handling the coastal trade at the present time, and where it will advantage the country to force a shipbuilding industry by killing the coal industry, it is rather difficult to see. It is said that schooners cannot get cargo, because they are forestalled by the larger ships. There is a pier at Glace Bay which does nothing else but load schooners with coal all day long, and the Dominion Coal Company run an advertisement through the newspapers asking for schooners to load coal in any quantity.

A most interesting and valuable contribution has been made to industrial and sociological literature by a work, entitled "Diseases of Occupation," from the pen of Dr. Thomas Oliver, of Durham University. Dr. Oliver is well-known in connection with his labors for the British Home Office, and the present work deals thoroughly with every phase of industrial disease, from "a legislative, social and medical point of view," as the sub-title of the book states. The work is written so that it can be read and appreciated by those who are not medical men, but who happen to be associated with the industries that Dr. Oliver passes under review. Great interest centres around literature of this

kind in view of the present trend of legislation, particularly in respect to the various laws that propose the shortening of hours of labor and the compensation of industrial victims. Dr. Oliver deals squarely and impartially with both the responsibilities of the employer and the employed. A few extracts from Dr. Oliver's treatise may not be without interest to the readers of the Journal, as they relate to mining and miner's diseases.

Regarding the much-debated question of the general health of coal miners Dr. Oliver says: "Of all occupations, none is more hereditary than that of coal mining. A lad goes into the mine because his father is working there and his grandfather did so before him. Miners are, therefore, not a selected class of men. Although a large part of the day is spent underground, the occupation of the miner is not an unhealthy one. . . . When pulmonary tuberculosis is caught by a miner, it is much more likely that the infection has been caught in the home or public-house than in the pit, where the ventilation is ramarkably free and the air supplied particularly pure and abundant. Better housing, the provision of purer drinking water, better food, good wages, greater railway facilities, and the establishment of reading and recreation rooms have done much to improve the health of the mining classes, and to raise their tone socially and morally."

On the question of whether coal-dust is or is not antiseptic the book goes on to say: "Experimental results, also surgical experience of miners' accidents, have suggested that coal-dust possesses a distinctly germicidal action, but when this has been tested on various forms of micro-organisms, including tubercle bacilli, no such germicidal action has been found." Dr. Oliver is of the opinion that the improved health of the miner and his comparative freedom from pulmonary tuberculosis are due to the better ventilation of the coal mines, the air of which, as it passes onwards through the mine, "becomes rid of bacteria and reaches the miner at his work in a purer state than the air we breathe in the streets of a large town."

Some of the miners' diseases to which the treatise refers are more particularly incidental to longwall and hand pick mining in thin seams, where the constrained and unnatural position of the miner induce such conditions as "beat knee," and "miners' nystagmus." The introduction of machinery, such as coal-cutters and longwall conveyors, is likely to render many of these conditions less frequent in the coal seams of the Old World, and on this side the water we have not yet got down to the working of the thinner seams.

Dr. Oliver refers to the unpleasant consequences that may follow the neglect of purulent opthalmia, or trachoma, in mining districts, and speaks of the spread of the disease to the wives and families of miners in Westphalia. Referring to the possibility of the introduction of this disease into Britain, Dr. Oliver says it can only arise "through alien immigrants bringing it." It is a matter of congratulation that the Canadian authorities are rigorous in this matter, but nevertheless we have reason to know that there are many cases of this disease amongst the mining populations of this country

Judging from Dr. Oliver's description the conditions of the gold workers in the Rand shows more need for improvement than any other set of mining conditions that exist in the Empire. It would be hard to imagine a worse state of affairs than have existed in South Africa, and although some improvement is taking place it is very slow.

A very complete chapter is devoted to amkylostomiasis, in which we are glad to find Dr. Oliver believes that solutions of common salt are of great value in preventing the development of the ova of the parasite to the larval stage. In most of the Cape Breton mines that underlie the sea there is present mine water of a more or less saline nature. Dr. Oliver states that the points which have struck him in regard to ankylostomiasis are: "The silent march of the disease from mine to mine and from one mining centre to another, the long latent period of its incubation, the suddenness of its outbursts, and the extreme virulence of the endemic when it first appears compared with what it is later on."

The last chapter in the book is devoted to the consideration of rescue work in mines. Dr. Oliver lays stress upon the fact that by far the greater number of victims in mine explosions die from carbon monoxide poisoning, and not from the shattering and burning effects of the explosion. He reviews the various forms of rescue apparatus now on the market, and closes with the remark that any doubts as to the utility of rescue apparatus should be removed in view of the following: "On September 14th, 1907, an explosion occurred in the Saar and Mosel Colliery at Merlbach, in the Prussian Saar district. A rescue party of 12 men, equipped with the Draeger apparatus, descended, and after working for an hour, brought to the surface the eight survivors and the bodies of four men who had been killed by the explosion." Dr. Oliver also remarks that the subject is one to which medical men engaged in colliery practice should give attention.

On the subject of intemperance Dr. Oliver does not mince his words. To quote: "There is nothing that induces to certain forms of industrial poisoning, or is more likely to become a source of accident to a workman than indulgence in alcohol . . . to this cause may be traced many of the accidents that happen in docks and wharves, and to it, also, probably some of the shipwrecks that have taken place shortly after vessels have put to sea. . . . It is not improbable that many of the unexplained falls of men, which may result in serious injury to life and limb, may be the result of ill-nourished, poisoned conditions of the nervous system, not the outcome of an immediate debauch, but of the long continued indulgence in alcohol. If we add to alcohol the infection of syphilis we have in these a combination of circumstances, the influence of which, from a medico-legal point of view, is far-reaching, so far as workmen's compensation is concerned."

It is a pleasant feature of this work that many of the diseases which Dr. Oliver has to refer to have been mitigated by improved conditions and industrial legislation. There are still many crying evils connected with child and female labor that require removing, both in America and in Europe, but on the whole, the book is one that makes for optimism, and is a strong plea for mutual consideration between capital and labor.

Diseases of Occupation, from the Legislative, Social and Medical Points of View. By Thomas Oliver, M.D., F.R.C.P. Methven & Co., London. Price, 10s. 6d.

ONTARIO.

Cobalt.

The Leasing System of Cobalt.—The Leasing System, which is rapidly gaining favor in the camp, will do much to solve the problem of the development of the large area in the proven district held by individuals or companies without funds to run their properties.

This system, which is universal in Western camps, was introduced in Cobalt by the Peterson Lake Mining Company, which now has a number of 10x20 acre plots leased to various companies and syndicates.

The Nova Scotia Company are now taking high grade ore from a plot leased to them by the Peterson Lake Company. The Little Nipissing is working a very promising lease situated on the east shore of the lake. Segsworth & Jackman, The Kerry Mining Company, The Gould Syndicate, and The Bridge Syndicate are all operating properties leased from the Peterson Lake Company.

A syndicate of Montreal capitalists, represented in Cobalt by A. M. Bilsky, have secured a number of important leases, and are negotiating for others.

Two twenty-acre lots north of and adjoining the Shamrock, Badger and Fisher-Eplett, owned by the Davis Silver Cobalt Mines Company, have been leased to this syndicate, which also has leased the Silver Mountain and Silver Nugget properties.

Mr. L. D. Madden, who has been a strong advocate of this method of development, in addition to arranging the Little Nipissing lease, has secured a ten-year lease from the Coleman Cobalt Company of a forty-acre plot, which adjoins the Nipissing Silver Leaf and White Silver, upon which he has already made a very promising discovery. Mr. H. P. Davis, in conjunction with one of the members of the syndicate which controls the Davis Silver Cobalt Mining Company, has taken a lease on Lot 5 of this company, and is working a large force of men. Mr. Davis is also negotiating leases in two additional properties belonging to the same company. The majority of these leases are for five years, with a royalty of 25 per cent. of the net smelter returns.

Nova Scotia.—After many months of development work carried on under more or less discouraging circumstances the Nova Scotia Mine is in a very favorable condition for steady shipments of very rich ore.

While many pockets of high grade ore were located in the 1,800 to 2,000 feet of underground work, no permanent ore bodies were located until this spring. The present position of this mine, as one of the big shippers is due to the efficient management and the continued faith of the directors in the property.

In the early part of this year in a cross-cut at the 100-foot level, vein No. 3, a very wide body of high-grade ore was encountered. A drift 200 feet in length, extending into the 30-acre tract, leased by this company from the Peterson Lake Mining Company, has developed a continuous ore body from 5 to 15 feet in width in which the values occur as leaf silver shot through the ore chute. A winze sunk on this chute proves the continuance of the values to this depth, and there should be 50 feet of good stoping ground above the 100-foot level. 100-foot level.

The last report of Mr. Benj. B. Lawrence, consulting engineer for the Nova Scotia Company, gives a concise and clear statement of the physical condition of the property, which should inspire the confidence of the stockholders in the management and the future of the mine.

Approximately $75,000 has been invested in surface plant and buildings, with the result that this property is one of the best equipped in the district. A comprehensive system of handling and tractment of the ore has been worked out, and from present indications, this mine should soon rate as one of the important shippers of the camp.

Northern Customs Concentrator.—Under the efficient management of Mr. F. J. Bourne, the Northern Customs Concentrator, is successfully handling on an average of 85 tons of low grade ore per day.

Over 4,500 tons of ore from the dumps of the Silver Queen, Townsite, City of Cobalt Mines have been treated since July, when operations were started. The mill runs 24 hours per day and only five and one-half hours have been lost in this time.

A self-dumping skip carries ore to a No. 4 Gates gyratory crusher, which reduces the rock to 1½-inch mesh, from the crusher it goes to a pair of 16" x 24" rolls, and is crushed to a ¾ inch size, elevated to a 36 by 60-inch trommel, and then separated; the over size is treated on a 24 x 30 Bull Jig, the tailings being sent to a battery of twenty 1,250-pound stamps, which reduce the materials to a pulp.

The pulp is taken to two Richard Classifiers, the coarse material going to Wilfley tables, and the overflow to callow settling tanks. The material from these tanks is treated on 5 by 6 Frue Vanners.

The rock handled by this mill is chiefly the dumps from the various mines, which have contracts with the Northern Concentrator Company, and averages 30 ounces of silver to the ton.

The recovery is approximately 84 per cent. Ore as low as 10 ounces to the ton can be handled at a profit.

Mr. Bourne is now installing an amalgamating and cyaniding process to save the small percentage of silver which is lost in the mill.

The mill is saving a large percentage of the argentite and pyrargrite by taking it out as a hutch product on the jig. This is re-treated in Keivies, or half barrels, and brought up to about 1,100 ounces silver. The losses in argentine and pyrargyrite are largely due to slimes. By treating in Keivies the losses due to attrition in jigs is avoided.

Cobalt Central.—On October 22nd a diamond drill which has been operating for some days at the Cobalt Central property, located at the two hundred-foot level a two-foot vein of calcite, smaltite and silver, which assays about six hundred ounces. A cross-cut will be run from the main drift at the lower level to cut this vein.

Chambers Ferland.—The "Right of Way," "La Rose" vein, was located on the Chambers Ferland property on October 20th, in a cross-cut from the "Right of Way" drift. This cross-cut was run at the expense of the Chambers Ferland Company to locate this vein on their property. The ore, were encountered, was forty-five inches wide and was very rich in silver.

Montreal River.—A contract has been let and work begun on a road from Elk City to Miller Lake. This road will be twenty-five miles in length and wil open up the Miller Lake, Lost Lake and Gowganda Districts.

Queen Alexandra.—A contract has been let to sink a shaft fifty feet deep on the Queen Alexandra property on the north shore of Cross Lake.

Coniagas.—The regular quarterly dividend of 3 per cent. will be paid November 2nd to shareholders of record of October 20th.

Little Nipissing.—At the annual meeting of the Little Nipissing Mining Company, held in Toronto, October 16th, it was unanimously agreed to increase the capitalization of the company from $650,000 to $1,000,000. The 350,000 shares were underwritten by the shareholders.

The report of Superintendent Madden, who has had charge of the development of the various properties of the company, was most encouraging.

The recent discovery of a 12-inch vein of decomposed calcite and cobalite near the north boundary line of J. B. 2, the orinal property of the Little Nipissing Company, is very promising, and has very good prospects of proving up shipping values.

Silver Leaf.—At a meeting of the directors of the Silver Leaf Mining Company in Toronto, October 17th, it was agreed to cancel the lease under which Mr. H. D. Symmes has been operating the property for the past year. The lase expires on October 21st, and after that date the property will be under the management of Mr. George Leyson, formerly superintendent of the Silver Queen.

Mr. Leyson will take charge under very much more favorable circumstances than confronted Mr. Symmes a year ago.

The company now has nearly $100,000 in the treasury, and ore in sight in the No. 5 vein, upon which a shaft has been sunk to the depth of 215 feet.

Temiskaming Cobalt (Warner Property).—A syndicate of Chicago people has purchased the Warner or Temiskaming Cobalt property on the shore of Lake Temiskaming, south of Haileybury.

Several shipments of ore, which run very high in cobalt, have been made from this property. A shaft has been sunk 125 feet on a big vein of cobalt. A new plant, consisting of a 12 inch drill compresser, boilers, etc., will be installed at once.

Cochrane Cobalt.—Under the direction of Mr. Floyd Harmon, operations have commenced on the Cochrane Cobalt property, south of the Temiskaming.

Columbus Cobalt.—A contract has been let to sink the main shaft on the Columbus Cobalt an additional 50 feet to the 200-foot level.

Leases.—Lots No. 388 and 389 an dthe Station Grounds at Cobalt, a total of 16 acres, have been leased from the T. & N. O. R. R. by A. Rosenthal and G. B. Dickson, of Ottawa.

The Davis Silver Cobalt Mines Co. have leased a twenty ore lot, south of Cross Lake, to a Montreal syndicate.

BRITISH COLUMBIA.

Phoenix.

Former Manager P. F. Roosa, of the Dominion Copper Co., has been appointed provisional liquidator for the purpose of winding up the affairs of that concern. It is regrettable that this company found it impossible to raise the money to pay the $80,000 that was due the bondholders for interest and payment toward the sinking fund, but it is conceded that the company would have, at best, worked along in a half-hearted way as long as copper remained at its present low figure, and, perhaps, after going through the fire of reorganization the affairs of the company will be in a more pure condition, and their finances will be placed on a firmer basis. The mines of the Dominion Copper Co. are looking well, and they had got their mining and smeltnig costs down to a lower figure lately than they have hitherto been able to do. It is true that there are a few facilities that might be installed at the mines and smelter, and which would materially reduce the cost of mining and smelting, but the management had long recognized this and these appliances would now be installed if they had ben able to find the money to do the work. A greater part of the equipment is up-to-date, such as air-compressors, drills, larger furnaces at the smelter, etc. No doubt when the present difficulties have been arranged the company will resume work with the prices of metals ascending, and as they will, no doubt, get a substantial start, the company should rapidly arive at a profit-paying stage and rank with the other dividend paying low-grade copper mines now working in the Boundary district If it is possible those interested are going to resume work within the next few weeks, but it is hardly likely that they will get matters in proper form in such a short space of time Some of the men have not been paid their wages yet, having only received time checks for their time; the principal issue at this moment is to get these men paid up. A small crew has been retained around the mines and smelter, to keep the mines unwatered, etc.

The unsettled condition of Dominion Copper affairs has, to a more or less extent, affected all of the mining interests of this district, which is only natural, and the result can be seen in the ore shipment during the past four weeks, which have shown a steady decline in tonnage, with the exception of the last week, ending October 17th, when the increase of 2,501 tons over the preceding week is recorded. The total tonnage for that week being 30,301 tons. Shipments from the Mother Lode, and particularly from the Oro Denoro, have been somewhat arratic during the last few weeks. Shipments from the Snowshoe have been steady, and during the week ending October 10th ran up to 2,730 tons.

The management of the Jewel mine have got the new site for the stamp mill cleared, and the ground is ready for the foundation of the building. There is a large tonnage of concentrating ore in the Jewel mine, but it is of a recalcitrant character. However, after a number of tests the company is satisfied the method they will employ in the new mill will be a success.

The bond until recently held by Hedley mining men on the Golden Zone has been thrown up, and it is stated that the deal will not be put through. From lack of water the recently installed stamp mill is now inoperative.

The Granby report is to hand, and shows that their profits for the fiscal year, ending June 30th, 1908, were $354,424 on a gross earning of $3,790,184. This company realized an average price of 13 1-3c. per lb. on fine copper during the year, while the net cost per pound, after deducting values of gold and silver, was $131. It is shown that the average extraction per ton of ore was 23.42 lb. copper, .2865 oz. silver and .0454 oz. gold.

A force of eight men has been put to work on the recently acquired B. C. Copper property in Wellington camp The 35-ft. shaft is all in ore, and is looking richer with ever shot fired, all of which must be very gratifying to both the bondholders and the bondors.

A new land of high grade ore has been cut in the workings of the Sally mine.

Rossland.

The report of the Consolidated Mining and Smelting Co. of Canada, Limited, has been published here, and is regarded as a good report for a year into which so much trouble was crowded as that which the report covers. Naturally, if the metal market had not gone to pieces last year the Consolidated Co. would have made nearly $400,000 more in selling the large quantity of custom ore and ore from their own mines that they had on hand at that time. As it was the profits on the year's operations were $43,415.93. This concern paid $66,940 in dividends during the year, and wrote off a large amount for depreciation of plant, stores, equipment and doubtful bills. It is pleasing to note that operations at the Trail smelter and lead refinery were increased 45 per cent. during the year, the value of the output being $5,425,501, as against $3,786,146 for the year 1907. According to the report (and according to local reports) the mines have large reserves of ore, development work is in good condition and the future looks bright.

The lessees of the Evening Star have uncovered a new ledge from which they aer shipping some rich ore. Assays recently taken show values of $28 to $50 per ton. The lessees shipped a 35-ton car during the week ending October 10th.

The lessees of the Nest Egg got a car of select ore off to the smelter during the last week, placing that mine on the shipping list for the first time this year.

Active work is going on at the Centre Star, Le Roi, Le Roi 2, Limited, Giant California, and many of the smaller properties, and the situation here presents a very stable appearance.

Nelson.

At the Spokane Interstate Exposition, October 5th to October 10th, the Nelson Board of Trade, competing with Montana, Idaho and Washington was successful in taking the $100 trophy cup for a general ore display. Nelsonians generally feel proud of this achievement, but there were other sections of British Columbia honored with cups and some with diplomas. The following were granted cups for their ore displays: Similkameen, Columbia Copper Mining Co.; Kamloops, Iron Mask mine; Boundary, Ore Denore of B. C. Copper Co.; Rossland, Centre Star mine; Nelson, Queen Victoria mine; Ainsworth, Krao mine; Kaslo-Slocan, B. C. Standard; one cup being awarded each display deserving of this honor in any one section. Montana, Idaho and Washington mines also competed in this class and carried off nine of the sixteen that were to be alloted. The following British Columbia mines were awarded diplomas: Lucky Strike, Kamloops; Evening Star, Kamloops; Roach River group, Similkameen; Elkhorn, Boundary; Arlington, Nelson; Granite Poorman, Nelson; Blue Bird, Kaslo-Slocan; Blue Bell, Ainsworth; Broadview and Mammoth, Camborne, from which it will be seen that our mines also took ten of the 22 diplomas that were awarded.

The talk of the Slocan is the strike that the Italian lessees of the Reco have made. They have more ore than they can conveniently handle with existing facilities. These fortunate men have been offered $25,000 for their lease, but refused to sell. A couple of strikes of this character and Sandon will take on some of its old-time liveliness.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax.—The Waverley plant of the Acadia Powder Company has been purchased by the Nobels. This is a significant step, and, no doubt, indicates an expansion of the industry.

Halifax.—Three new gold-mining enterprises will be launched this autumn, and three abandoned mines will be put in commission.

Amherst.—The new bankhead of the Maritime Coal, Railway and Power Company has a capacity of 1,500 tons per day. It is equipped with revolving tipples, automatic quick-weighing hoppers, etc.

ONTARIO.

Cobalt.—The results of the tenders for the four parcels of Cobalt land were announced on October 15th by the T. & N. O. Railway Commissioners. Messrs. A. Rosenthal and G. P. Dickson, of Ottawa, have secured parcels one and five, comprising sixteen acres at the Cobalt station grounds, and lots 388 and 389 of the townsite. The price paid for this was $30,200. The other two parcels, comprising about four acress of lot 44 in the town and lot 338 were secured by Messrs. W. L. Hayden and Raymond Mancha, of Detroit, for $5,575. There is a royalty of 25 per cent. on the gross output of the properties. The payments were made on a 999 years' lease.

The Floyd mine (so-called), a mere prospect, is being manipulated in Montreal. Those who think that this is a mine should come up to Cobalt and have a look for themselves.

Larder Lake.—The projected sale of the Harris-Maxwell gold mine is not yet completed. A month's test run in the stamp-mill is to be made.

Cobalt.—It is reported that a compromise has been effected between the Ontario Government and the Temiskaming and Hudson Bay Mining Company. The T. & H. B. receives patents for the property under dispute, and the Government is to be paid 15 per cent. of all smelter receipts.

The Nova Scotia mine has done about 5,000 feet of drifting, along with 2,500 feet of cross-cutting since it was opend.

Bruce Mines.—The Bruce copper mine was sold at auction early in October. The highest bidder was Mr. R. W. Leonard, of St. Catharines. Mr. Leonard's bid was $50,100. Associated with Mr. Leonard is Mr. Alexander Longwell. The Bruce mine has ample low grade ore reserves. The question of concentration has hitherto been a leading difficulty.

BRITISH COLUMBIA.

Phoenix.—P. F. Roosa, local manager of the Dominion Copper Company, has been appointed receiver. The appointment was made on the application of the National Trust Company of Toronto.

Hazelton.—Five miles below Telkwa, on the Berkley River, a four-foot seam of clean coking coal was found some weeks ago. Another seam, 8 feet thick, was discovered 1,000 feet above the first one.

Grand Forks.—No. 1 Furnace of the Granby Consolidated has been put in blast. It has been enlarged and is now four feet larger and four feet deeper than any of its companion furnaces. This change in construction is experimental. If No. 1 proves successful the other furnaces will be similarly enlarged.

Kamloops.—At the Interstate Fair at Spokane the mineral exhibit from Kamloops was one of the striking features. The specimens from the Iron Mask mine won a prize in Class 2. The prize consisted of a silver cup. A similar prize in Class 1 was awarded the display from Nelson. Other B. C. camps and mines won distinction.

Victoria.—The C. P. R. freight steamer, "Princess Ena," is carrying about 1,300 tons of copper over from Sidney Inlet mines to the Tyce Copper Company's smelter. The Tyce people have leased the Sidney Inlet mines.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

Several strikes of coal miners in the South Wales coal field are reported over the questions of wage reduction, and the employment of non-unionists, and a large number of miners are out of work.

The amounts awarded for compensation under the Workmen's Compensation Act, in connection with the recent disaster at the Maypole pit, Abram, in which 75 lives were lost, will amount to a total of between £14,000 and £15,000.

A syndicate has been found for the proposed of quarrying the columnar basalt on the north coast of Antrim, Ireland, between Ballycastle and Portrush.

GERMANY.

It is reported that a large new colliery will shortly be established by Messrs. Krupp, of Essen, at Neuenkirchen, Westphalia.

The Gelsenkirchen Company propose to erect six blast furnaces and an extensive steel works, etc., at a cost of 40-000,000 marks at Roth Erda.

The death of Mr. Alexander Hilbek, one of the leading authorities on mining matters in the Rhenish-Westphalian coal field, is announced.

The Rhenish Boring Co. will immediately commence the development of 15 coal concessions on the left bank of the Rhine on the Dutch frontier.

ALGERIA.

The Ain-Arko zinc deposits, which were first worked in 1873, but subsequently abandoned, were reopened in 1904, and there is now a certainty of a large output from existing workings and good promise as regards other prospects.

SOUTH AFRICA.

The Simmer Deep mine, on the Rand, is now operated by power purchased from the Victoria Falls Power Co., which is a new departure involving the supply of electric energy from central stations on the Rand. Competition in the supplying of power for operating mines is anticipated.

The diamond-cutting and polishing industry has been started at Johannesburg on a small scale with a few experienced workers. It is intended to extend it as soon as the business has been fairly established, and to train young men in the art.

More white labor is being employed in the gold mines, the engagement of previously unskilled whites to take the place of natives having proved more successful latterly than at first. One result has been a diminution in gold thefts.

CUBA.

The gold mining industry is coming into prominence. The Holguin-Santiago Mine Co. has recently made large shipments, and has acquired new claims which show excellent prospects. Other enterprises are being undertaken in the Province of Santiago, where gold was formerly produced in paying quantities.

UNITED STATES.

It is estimated that the gold production of Rawhide, Nev., during the first year of the existence of the camp, will amount in value to about one million dollars.

The Iron River district of the Menominee Range, Mich., bids fair to prove an important source of iron ore supply. A number of new mines are in course of development and others are being opened.

The Philadelphia & Reading Coal and Iron Co. is installing rescue apparatus of the helmet type at all its collieries. The device is equipped with a tank of oxygen to last the wearer for two hours.

The Tintic Smelting Co., Utah, has closed down its plant for some weeks.

MEXICO.

A new holding company is reported in process of organization to take over the assets of the Greene Gold and Silver Co. and the Sierra Madre Land and Lumber Company, the bankruptcy of which was a serious blow to the industries of the State of Chihuahua. The Greene interests will not remain in control.

Progress in the mining industry in the State of Oaxaca is being indicated by the erection at several points of modern reduction works.

COMPANY NOTES.

The report presented at the annual general meeting of the Granby Consolidated Mining, Smelting and Power Company, Limited, held in New York in the former part of October, for the year ending June 30 last, shows that during the past year the big Boundary company made a profit of $354,424. The official figures are as follows:—

Pounds of copper	21,126,926
Ounces of silver	300,593
Ounces of gold	40,139
Gross earnings	$3,790,184
Charges, etc.	3,435,760
Net profit	354,424
Dividends	675,000
Deficit	$320,576
Previous surplus	2,775,757
Profit and loss surplus	$2,455,181

The charges as above include the following items: Making expenses at mines and smelter, freight, refining, selling and general expenses, $3,013,395; foreign ore purchased, $170,266; bonus to employees, $23,100; and allowing for depreciation, $228,999.

Crediting surplus after charges, etc., $354,424, with the $228,999 charged out for depreciation, the amount earned on the stock for the year was $583,423, or $4.32 per cent. on the $13,500,000 outstanding.

The general balance sheet for the year shows as follows:—

Assets.

Cost of land, real estate, machinery, buildings, dwellings and equipment	$15,238,437
Stocks, bonds, and bills receivable	1,008,012
Fuel and store supplies	185,324
Cash and copper	421,625
Total	$16,853,399

Liabilities.

Capital stock issued	$13,500,000
Dividends collected on liquidated shares	1,323
Accounts and bills payable	896,895
Surplus	2,455,181
Total	$16,853,399

The price realized on fine copper was on an average 13 1-3 cents per pound, and an average for gold of $20 per ounce.

The net cost of copper per pound, after deucting the gold and silver values, was 10.31 cents.

The address of President Longcloth in part runs thus: The mechanical devices now in operation, such as shafts, hoists, belt conveyers, mine cars and electric locomotives, are able to handle about 5,000 tons of ore daily. The mines shipped to the smelter during the past year a total of 858,432 tons, as against 644,549 tons during the previous year. The grade of ore mined was not as good as in the previous year, carrying about one pound less of copper and from 10 to 12 cents less per ton of ore in gold and silver.

The extraction per ton o fore on the average was 23.42 pounds copper, .2865 ounces silver, and .0503 ounces of gold during the previous year. During the summer months a lower grade ore was shipped, due to mining the glory holes on the surface, which are low-grade and which cannot be mined during the winter months. Consequently the ores will average richer in winter and spring and poorer in summer and fall. The quantity of ore developed by diamond drilling has been greater than the ore extracted.

The total tonnage of Granby and foreign ore amounted to 882,611 dry tons, as compared with 665,915 in the previous year, and there was produced 21,120,926 pounds of copper as against 16,403,497 pounds during 1906-1907.

The cost per pound of copper produced, after deucting the gold and silver values, was $0.1024 as against $0.1014 in the previous year.

Almost immediately after issuing our last annual report a most severe panic broke out, and among other disastrous consequences the consumption of all metals decreased materially, and prices showed a heavy decline. Prices fell off from about 17 cents to close to 12 cents, and showed little recovery during the first six months of the present year, due to the great falling off in the consumptive demand for home trade. Fortunately, Europe was a continuous buyer, thereby preventing large accumulations of stock. Of late the demand for home trade has shown great improvement, and if this continues, as appears to be the case, it may be confidently hoped that prices will show a further improvement.

The enormous decline in the price of copper and the marked influence on the cost by reason of the difficulties with which the smelter had to contend, permitted the declaring of only two dividends, namely: One of three per cent. on September 30, 1907, and one of two per cent. on June 30, 1908.

ANNUAL MEETING OF THE CITY OF COBALT MINING COMPANY.

The annual shareholders' meeting of the City of Cobalt Mining Company was held on the evening of October 9th. Mr. E.

T. Shillington, M.L.A., was elected president, Mr. H. H. Long vice-president, and Mr. W. H. Powell second vice-president. Mr. B. W. Leyson, of the Townsite Mining Company, was appointed mining superintendent, and the position of manager was abolished. The following statement of liabilities and assets was accepted:—

Liabilities.

Capital stock of the company		$500,000 00
Outstanding accounts		7,924 19
Royalty due T. & N. O. Ry. Commission		40,000 00
Pay list, September, men	$6,603 92	
Pay list, September, office	425 00	
		7,038 92
To balance		1,162,818 38
		$1,717,781 49

Assets.

Office furniture, etc.		$600 00
Tool account		1,900 52
Buildings		6,772 03
Real estate		16,695 69
Plant account		14,272 04
Treasury stock not issued		48,783 00
Estimated value of mine as at present developed		1,500,000 00
Value of ore not shipped		13,000 00
Ore shipped to smelters and not yet accounted for, estimated		69,850 00
Cash on hand	$49 50	
Balance in bank	45,858 71	
		45,908 21
		$1,717,781 49
By balance		$1,162,818 38

STATISTICS AND RETURNS.

NOVA SCOTIA STEEL.

The coal shipments of the Nova Scotia Steel Company for the past nine months show an increase of 15,779 tons, as follows:—

Shipments September, 1908	56,367
Shipments September, 1907	60,355
Decrease September, 1908	3,988
Shipments 9 months, 1908	481,011
Shipments 9 months, 1907	465,232
Increase 9 months, 1908	15,779

Coal shipments from the collieries of the Cumberland Railway and Coal Company, Springfield, N.S., for September, amounted to 29,442 tons.

INTERCOLONIAL COAL CO.

Shipments, September, 1908	20,628
Shipments, September, 1907	21,003
Decrease, September, 1908	375
Shipments, nine months, 1908	191,992
Shipments, nine months, 1907	202,574
Decrease, nine months, 1908	10,582

INVERNESS RAILWAY & COAL CO.

Shipments, August, 1908	20,487
Shipments, August, 1907	22,422
Decrease, August, 1908	1,935

Coke production—First nine months, 1907	162,459 "
Output of coal, week ending October 16	19,202 "
Being a daily average of	3,200 "

Reports to the Provincial Bureau of Mines for the six months ending June 30 show that the metalliferous mines and works in the Province produced over eight million dollars worth of ore. The classification is as follows: Arsenic, 256 tons, value $1,573; cobalt, 365 tons, value $39,822; gold, 1,524 ounces, value $27,672; silver, 7,746,537 ounces, value $3,888,991; copper, 3,887 tons, value $547,417; nickel, 4,779 tons, value $932,828; iron ore, 84,440 tons, value $214,284; iron pyrites, 8,728 tons, value $27,968; pig iron, 148,365 tons, value $2,401,709. The total value is $8,083,264.

Following are the figures of German consumption of foreign copper for the months of January and August, 1908:

Imports of copper	107,387 tons.
Exports of copper	5,442 "
Consumption of copper	101,945 "

As compared with consumption during the same period in 1907 of 78,409 tons. Of this quantity 99,211 tons were imported from the United States. Reported by L. Voleglstein / Co., New York.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1st to date:

	Week end. Oct. 10. Ore in lbs.	Since Jan. 1. Ore in lbs.
*Cobalt Central	40,500	[illegible]
Kerr Lake	80,000	846,174
La Rose	120,000	6,490,640
Nipissing	260,200	[illegible]
O'Brien	191,260	5,463,647
Temiskaming	60,000	[illegible]
T. & H. B.	180,000	1,648,500

*Concentrates.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, B.C., Oct. 10.—The total shipments for the week were 34,332 tons, and for the year to date 1,359,186 tons. The

weekly shipments show a considerable falling off, as far as the totals are concerned. This is due to repair and extension work going on at the Granby Smelter, the output from those works being less than two-thirds of the capacity of the plant. On the other hand, the Trail Smelter, through the operation of its new furnace, handled more ore last week than at any time during its history, 9,220 tons. Several properties have recommenced shipping in each one of the principal divisions of the district.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January to date:

	Week end. Oct. 17. Ore in lbs.	Since Jan. 1. Ore in lbs.
Buffalo	.....	912,950
**Coniagas	.....	969,360
Cobalt Lake	.....	341,683

Trethewey	.....	1,910,476
Watts	.....	561,680

*Concentrates. **Concentrates and high-grade ore.

The total shipments for the week were 967,470 pounds, or 483 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, B.C., Oct. 17.—The shipments for the week ending October 17 show considerable activity in mining over all the districts, several new shippers being added to the list. The total for the week is above the average for the year, but not nearly as much as the capacity of the smelters warrant. The Trail smelter is treating more ore than at any time during its history, and its receipts for the week establish a new record for the consolidated company.

The following are the ore shipments for the past week and year to date:—

BOUNDARY SHIPMENTS.

	Week.	Year.
Granby	18,069	820,844
Mother Lode	8,772	189,736
Oro Denoro	900	51,006
Snowshoe	3,491	14,339
Phoenix Amalgamated	56	85
Other mines	.....	22,248
Total	31,288	1,098,262

ROSSLAND SHIPMENTS.

Centre Star	4,023	134,996
Le Roi	1,685	62,483
Le Roi No. 2	530	23,550
Other mines	.....	982
Total	6,238	222,011

SLOCAN-KOOTENAY SHIPMENTS.

St. Eugene	726	19,643
Whitewater	45	1,471
Whitewater, milled	280	12,620
Poorman, milled	250	8,800
Queen, milled	400	7,790
North Star	69	3,364
Richmond	69	1,870
Arlington, Erie	24	1,870
Standard	42	1,102
Rambler-Cariboo	38	968
Silver Cup	51	742
Idaho	98	634
Ruth	21	618

Copper and Lead Mine

on Lake Superior, near Port Arthur, four hundred acres; old title; considerable developement done; good mineral showings; bargain price; easy terms on working option. For further particulars, apply to

W. L. HIME,

160 Dowling Ave., Toronto

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary, and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

NOW READY

Contains all the latest information up to within a few days of publication. The Standard Reference Work on Mines. 1,600 pages. In demy 8vo, cloth. Price 21/-, post free.

The book can be seen and obtained at the Offices of this paper.

Twenty-Second Year. Established in 1887.

The Mining Manual
For 1908
By WALTER R. SKINNER

22nd YEAR

A Record of Information concerning Mining Companies (Gold, Diamond, Silver, Copper, Tin, Iron, and other Mines, Collieries, Land, and Exploration Concerns, etc.)

Arranged in Three Sections, **Australasian, African, Miscellaneous,** with Tables of Crushings at ends of Sections, followed by List of Mining **Directors and Secretaries,** their Names, Addresses, and Descriptions, and Names of the Companies with which they are connected; also **Mining and Consulting Engineers and Mine Managers,** with their Company connections, and a **Dictionary of Mining Terms.**

THE MINING MANUAL FOR 1908 contains particulars of no less than 3,100 COMPANIES, arranged in three sections, 450 Companies being AUSTRALASIAN; 1,050 AFRICAN; and 1,600 MISCELLANEOUS (including Siberian, Mexican, Indian, Canadian, American, etc., and the Coal, Iron, and other mining concerns of the United Kingdom). The particulars given of each Company include the Directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; position at mine and ore reserves; details of capital; calls; dividends paid; and the financial position as disclosed by the accounts.

The Lists of Directors (over 7,000) and Secretaries (1,750) include their addresses and descriptions and names of the Companies with which each particular Director or Secretary is connected.

A complete Alphabetical Index, including many useful items of reference, occupies 40 pages.

FACULTY OF APPLIED SCIENCE AND ENGINEERING

Courses in

1. Civil Engineering.
2. Mining Engineering.
3. Mechanical and Electrical Engineering.
4. Architecture.
5. Analytical and Applied Chemistry.
6. Chemical Engineering.

Diploma granted at the end of three years B. A. Sc. at the end of one additional year.

Professional Degrees:

Civil Engineer (C. E.)
Mining Engineer (M. E.)
Mechanical Engineer (M. E.)
Electrical Engineer (E. E.)
Chemical Engineer (C.E.)

For Calendar and other information apply to the Secretary

A. T. LAING.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which contains an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

A VARIABLE DEMAND

for air power, in mining service, may be met with economy and reliability by the use of Sullivan Duplex Self-oiling Air Compressors.

The steam driven machines of this type (illustrated above) are able to start without attention, thus proportioning the power used to the air supply required. The steam distribution is controlled by a hand-adjusted cut-off.

The main bearings, crossheads and eccentrics are housed, to exclude grit and dust and are oiled automatically from central tanks.

The use of two-stage air cylinders, with large water jackets and an intercooler, secures high air efficiency.

They are built in 5 styles (3 steam and 2 belt driven) and in capacities from 150 to 2,500 cubit feet per minute.

Our new compressor catalog is now ready for circulation. This book contains over 100 pages of information of interest to mining and manufacturing men. Among the more important articles is one on the selection of a steam driven compressor. The questions of lubrication, air coolings and regulation are thoroughly dealt with, and all standard machines are listed.

GOOD HUNTING

The finest hunting grounds in Canada—for big game and small game, are reached by the Canadian Pacific Railway. Amongst the best must be reckoned the country adjacent to the recently opened Toronto-Sudbury line—alive with moose, deer, bear and every variety of game. This will be the first Fall this country has been accessible by rail. Go up while the hunting is at its best.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLER

Provincial Geologist of Ontario, formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, now in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

THE CANADA IRON CORPORATION, LIMITED.

We have before us the abridged prospectus of the Canada Iron Corporation, Limited, a document both interesting and significant.

The new organization, whose principal officers are gentlemen prominent in Canadian industrial life, is essentially a consolidation of going concerns. For a long time the Messrs. Drummond, of Montreal, have been identified with the growing iron industry of the Dominion. Gradually their holdings have increased and their interests have widened. They and their associates now control several blast furnace plants, pipe foundries, general foundries, and car-wheel foundries in Nova Scotia, Quebec, and Ontario, and almost inexhaustible iron ore deposits in Ontario, New Brunswick, and Nova Scotia. The contemplated addition of steel works will complete the cycle.

The capitalization of the corporation is $8,000,000. The estimated annual profits on the earnings of the mines, furnaces, and foundries is set down as approximately $600,000.

From October 26th to October 29th, inclusive, £364,000 of the issue of £500,000 of six per cent. first mortgage sterling bonds was offered for subscription in London.

We feel no hesitation in expressing our belief that the Canada Iron Corporation, Limited, deserves the support of British and Canadian investors. The assets of the corporation are positive, and will increase in value and earning power. The corporation's plants are so placed that they command a full share of our expanding market. It is, indeed, imaginable that ere long the corporation will become a controlling factor in our iron trade.

Apart from the commercial value of plants and mines and the strategic importance of location, the names of the Montreal and London directors inspire cinfidence.

If we may be permitted to indulge in metaphor, we shall liken the three Messrs. Drummond to a well-balanced engine, in which Mr. J. J. Drummond is the fly-wheel, Mr. George E. Drummond the lubricator, and Mr. T. J. Drummond the governor.

With this engine soundly installed, we shall hope for great things for our iron industry.

THE PREVENTION OF MINE EXPLOSIONS.

We reprint in this number of the Canadian Mining Journal the "Report and Recommendations" of the three foreign experts engaged by the United States Department of the Interior to investigate coal mine explosions.

The three men selected to undertake this task are authorities of the highest standing. They fill respectively the offices of Inspector-General of Mines, Belgium; Councillor of Mines, Germany; and H. M. Inspector of Explosives, England.

The report marks a turning point in the history of coal mining in the United States. Heretofore the most frightful accidents have created but a temporary stir. The authorities at Washington have been apathetic, and their apathy has cost the nation thousands of useful lives. Now that the awakening has come, there is little doubt that complete measures will be adopted for the prevention of coal mine accidents.

The first step to be taken is the close inspection of explosives. Without this preliminary, all precautions are meaningless. Not only should permitted explosives be limited to those that pass satisfactory tests as to safety, but the maximum charge should be fixed by law, and uniform regulations as to handling, loading, and firing of explosives should be enforced at every colliery.

The second important measure is the universal introduction of safety lamps. There is little doubt that this will meet with opposition, especially from the workmen whose safety is being considered. There is no doubt that safety lamps are essential to the prevention of explosions.

Thirdly, it is of the most urgent importance that rescue apparatus be installed at all coal mining centres. We need not reiterate the arguments that justify this recommendation. The history of the great coal mining disasters of the past few years is conclusive proof of the justice of this statement.

Fourthly, there is much misapprehension as to the applicability and efficacy of mine-watering as a preventive of coal-dust explosions. We have referred more than once to the strong position taken by Mr. James Ashworth, who has condemned the belief that watering is a universal remedy. The question is one that requires full and searching inquiry.

Lastly, the prevention of mine explosions is a subject of international importance. Difficulties will not be solved, dangers will not be removed unless there is earnest co-operation between governments, operators, and employees.

The recommendations of Messrs. Desborough, Meissner, and Watteyne are timely. They will serve as a nucleus for further work. But we are disappointed at their lack of completeness. The omission of all mention of rescue apparatus is a serious oversight.

Before leaving this subject we desire to impress upon Canadian coal mine operators the need of keeping pace with this praiseworthy movement. And it is to be hoped that our Federal Department of Mines will give the matter attention at the earliest possible opportunity. Canada must not be last in adopting measures for the preservation of life.

THE COBALT BOOM.

An apparently well-grounded hope was entertained by sane mining men that this autumn's boom in Cobalt stocks would not exceed the bounds of reason and propriety. It was foreseen at least ten months ago that a boom was inevitable. But there seemed to be scant room for a recurrence of the crude robberies and "raw deals" that characterized the first boom.

The boom, however, has attained dimensions that are distinctly dangerous. The lessons of the last two years have been ignored or forgotten, and Cobalt stocks are playing over the financial sky like mad northern lights.

One effect of the boom of 1907 was that the legitimate exploitation of the undeveloped portions of Cobalt and of the Montreal River districts was retarded. For a time Cobalt became an object of contumely. Then, gradually, the clean work of clean men brought results, and an output of six million dollars' worth of silver was an argument not to be ignored.

Of the several hundred mining companies incorporated up to and during the year 1907 only about thirty now survive on a working basis. Not more than twenty of these have paid dividends. Several of the companies that have paid dividends were totally unprepared to maintain payments. Every one of the hundreds of flotations appealed to the public with rosy promises and hectic adjectives. A large number of the worst of these received the support of the Toronto World.

Glancing through the advertising columns of the Toronto World, which has constituted itself the chief tout for all classes of Cobalt and Montreal River wildcats, we notice that several new flotations, especially those that occupy advertising space, are given warm commendation in the special mining columns of this obviously purchasable sheet. It strikes one as being lamentably significant of journalistic turpitude that a paper of the World's standing uses its reading columns to misdirect and delude those whom it is supposed to protect. The readiness with which the World declares that a youthful promoter is an "acknowledged expert," or that a case-hardened faker is a "mining engineer of continental reputation," is pre-eminently painful.

The most enthusiastic friends of Cobalt and Montreal River will acknowledge that there are, especially in boom times, many crooked flotations foisted upon the public. Does the World ever damn any of these? Does it do anything but play into the hands of men whose dice are loaded and whose cards are marked?

This is a time when mining men and others are in duty bound to exercise discretion. There is nothing reprehensible in lending one's name to a mining project. But it is at least incumbent upon responsible citizens to make sure that there is no room for doubt as to the soundness of the concerns with which their

names are associated. Our attention has been drawn to the fact that Mr. James L. Hughes, Chief Inspector of Schools for Toronto, and Mr. J. Houston, superintendent of the Right of Way mine, have permitted their names to be used in connection with two recent flotations, one of which is considerably worse than the other. In all such instances as these the names of prominent men are of use to promoters merely as bait. And it is notorious that bait of this kind is most effective among doctors, school teachers, farmers, and laborers. Therefore a very grave responsibility devolves upon the shoulders of Mr. Hughes, who is an outstanding figure in educational circles, and upon Mr. Houston, who carries with him the prestige of a successful mine. In dealing with both of these gentlemen we wish to be frank. Of Mr. Hughes we say this: he is guilty of a major indiscretion when, as Chief Inspector of Schools, he uses his official standing to aid a precarious mining scheme. Mr. Houston's action we must deplore even more deeply.

In conclusion, it is obvious that the Ontario Companies Act is a dead letter. Not one of the mining advertisements published in Ontario papers conforms with the requirements of the Act. Not a few of the advertisements are direct breaches of the Act. Unless the Provincial authorities and decent mining men rise to the occasion at once, we shall have a recrudescence of such highway robberies as were perpetrated not long ago by Law and Russell.

RUSSIAN ASBESTOS.

It will be of interest to Canadian asbestos producers to learn that the principal asbestos deposits in the Urals have been sold to a German syndicate. The Korieff mine, the Pokleffsk mines, and the mines of Baron de Sukanton have passed into German hands. The Pokleffsk property includes the only mill operated in the whole region. The total annual output of the properties mentioned amounts to about 470,000 poods, or 8,460 short tons, which is more than eighty per cent. of Russia's whole yearly production.

This announcement gains an especial significance from the fact that Germany is the chief European consumer of Canadian asbestos.

A JAPANESE ENTERPRISE.

On Moresby Island, one of the Queen Charlotte group, lying off the shores of British Columbia, there is a promising copper mine. The ore deposit was discovered in May, 1906, by Mr. A. Ikeda, a Japanese merchant, who was at that time interested in the abalones fisheries. The history of the mine from that time to this is outlined by Mr. Ikeda on another page of this issue.

There are many unique features about the Ikeda mine. All of the employees, with the exception of five white men, are Japanese. The company was floated in Kobe and Osaka, Japan. One of its principal officers is Mr. Owaya, who is a member of the Japanese Diet. The company name is "Awaya-Ikeda."

Several residences and other buildings have been erected on the Awaya-Ikeda property. The Japanese miners, however, live in the old abandoned stern-wheeler "Dawson," built by the C. P. R. for service on the Stikine River. The manager, Mr. Ikeda, occupies the charthouse.

The Ikeda mine began shipping ore early. It is now producing at the rate of fifty tons per day. Its owners expect great things, and, apparently, they have made a healthy start.

NEOTERIC NICKEL.

Here is something new under the sun. A valued correspondent, whose letter is not printable, beseeches us to smite error in high places. He encloses, for our delectation, a clipping from our venerable London contemporary. The clipping is a paragraph on the metal nickel, and the paragraph is part and parcel of an article of a series entitled "The Recognition of Minerals."

Mr. C. G. Moor, M.A., F.I.C., the author of the article, disarms criticism by asking for correction and suggestions as to "a better way of dealing with the subjects touched upon." By way of proving that this request is not a superfluity, he writes thus of nickel:

> "One of the most important modern uses of nickel is to form the outer skin of rifle bullets. With modern rifles the rapidity of the bullet through the barrel is so great that a soft (lead) bullet would tend to strip and foul the rifling, and hence modern rifle bullets consist of a coating of nickel filled with lead.
>
> The principal ore of nickel mined at the present time is garnierite (also called noumeite).
>
> Garnierite (which has already been described under "Green Minerals") may also be greyish or nearly white, and sometimes a brown; to this variety the name "chocolite" has been given.
>
> Garnierite is mined in New Caledonia and at the Sudbury Mines, in Canada. Noumeite is essentially a silicate of nickel with magnesium silicate.
>
> The ore from Sudbury is silicate of nickel with some copper silicate. These are the two most important commercial ores."

One of the most important modern uses of education is to enable authors to ascertain a few facts about their chosen topics. Poets, lawyers, ladies, and promoters are privileged classes. But the man of science deals with ascertained facts. Ascertained facts concerning the occurrence of the nickel ores of Sudbury and New Caledonia are easily available.

Stern logic drives us to the conclusion that, since Mr. Moore is presumably neither a lawyer nor a pro-

moter, he must be either a poet or a lady. If the last alternative prove true, we forgive her. If the author be a poet, we demand hexameters in future.

"ROARING" STAMPS.

A writer in the Toronto Globe's special Cobalt supplement deals thus with the stamp-mill of the Muggley concentrator:—

"Every hour the 20 roaring stamps pounding down on the rock reduce 85 tons to pulp."

"Roaring" is good; "85 tons" per hour for 20 "roaring" stamps is better. Heretofore a duty of three to six tons per stamp in 24 hours has been accepted as a fair standard. But if the Globe's announcement be true, then are all other stamp-mills fit only for the scrap-heap. When each stamp has a crushing capacity of about 100 tons in 24 hours it is high time that laggards (who get only this duty out of twenty times one) and find out what's dong. Strange to relate, we believe that the Globe's announcement will be news to the proprietors of the Muggley mill.

After careful thought, we can attribute the remarkable capacity of the Muggley stamps (as announced by the Globe) to nothing but the "roaring" qualities of the stamps.

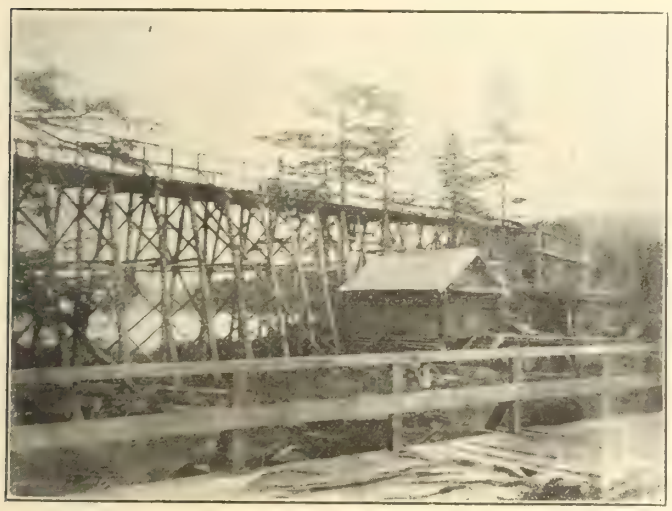
Thus science marches. In future all purchasers of stamp-mills will include in their specifications a carefully designed roar.

CANADIAN BANKING.

Collier's Weekly, American edition, for October 17, publishes this remarkable statement: "Canada guarantees bank-notes, but has not thought of guaranteeing deposits." Collier's is laboring under complete misapprehension. Canada does not guarantee bank-notes. Except in the case of the one dollar and two dollar notes (which are not bank-notes) issued by the Government, there is not one cent of gold behind our bank-notes. Depositors in the Postoffice saving bank are guaranteed. Depositors in chartered Canadian banks are not guaranteed.

IKEDA BAY MINE.

Written for The Canadian Mining Journal by A. Ikeda.



LILY MINE—FRONT VIEW OF No. 3 TUNNEL.

This property is situate on the southern end of Moresby Island in Ikeda Bay, one of the Queen Charlotte group, British Columbia. It is reached by C.P.R. steamer four times per month and is distant from Vancouver about 450 miles. It is distant from Jedway about three miles in the next bay north, which is now the seat of the Government Recorder and where all the claims on Queen Charlotte Islands are recorded. The town of Jedway has telephone connection with Ikeda Bay and is connected by good government trails. It also has a good sawmill, hotel, store, etc., all of which have been built within the last year or so. The Copper Queen, a very promising property, which is owned by Seattle people and where extensive drilling with dia-

mond drill is going on, also the Eagle Tree group of mines all are around Jedway, the latter property being under bond to the Tyee Copper Co., a wealthy English company. At Collison Bay, the next bay south of Ikeda Bay, there are some promising properties, notably the Meal Ticket, Thunder, and Maple Leaf groups, the latter, where development work is going on, being now under bond to some Bellingham Bay people.

Further north from Jedway, about 50 miles, is the "Swede" group, which is bonded for a large sum of money. This is a large low grade property having a very large vein of self fluxing ore and by some it is believed to be a larger property than even the Granby mines. Of course it will take development to prove this, but according to present indications it looks very favorable for it being another Granby. All the mines on the islands are blessed with easy transportation facilities, as the mountains come down fairly straight to the water where large steamers can load right from the bunkers. This fact alone makes these islands very enticing to mining people.

The climate on these islands is very mild, no snow or winter at all, although there is quite a bit of rain with high winds.

TRESTLE AND NO. 4 ORE BIN.

Geology.—Around Ikeda Bay and the south shore of Skincuttle Inlet are limestone and slate. The entire country surrounding Ikeda Bay is cut by dykes of greenstone and other igneous rocks, such as diorite. It has been subject to movements resulting in well defined fissures and also in slips or fissures at right angles to and between the main fissures. The main fissures are vertical, the others approximately horizontal. The horizontal fissures or slips are of great number and reach from one main fissure to another, following their plane along the main fissure. It is along the horizontal fissures that the largest ore bodies have been made.

The formation around Ikeda Bay is diorite and limestone.

Vein.—The vein is what is called a contact vein, having good and well-defined walls, carrying an average width of 5 feet and as wide as 30 feet in some places. The vein dips to the east at an angle of about 45 degrees.

Development.—The property is developed with four tunnels. The depth from the face of the lowest level to the outcrop is 300 feet. These levels are all connected with raises, etc. Greater depth than ever will now be attained on account of the elevation of the mountain. The faces of all tunnels will from now on make foot for foot in depth.

Area.—The entire number of mineral claims which this company own is 47, but the work is being almost entirely devoted to what is known as the Lilly group.

ORE BOAT LOADED WITH 1,000 TONS ORE.

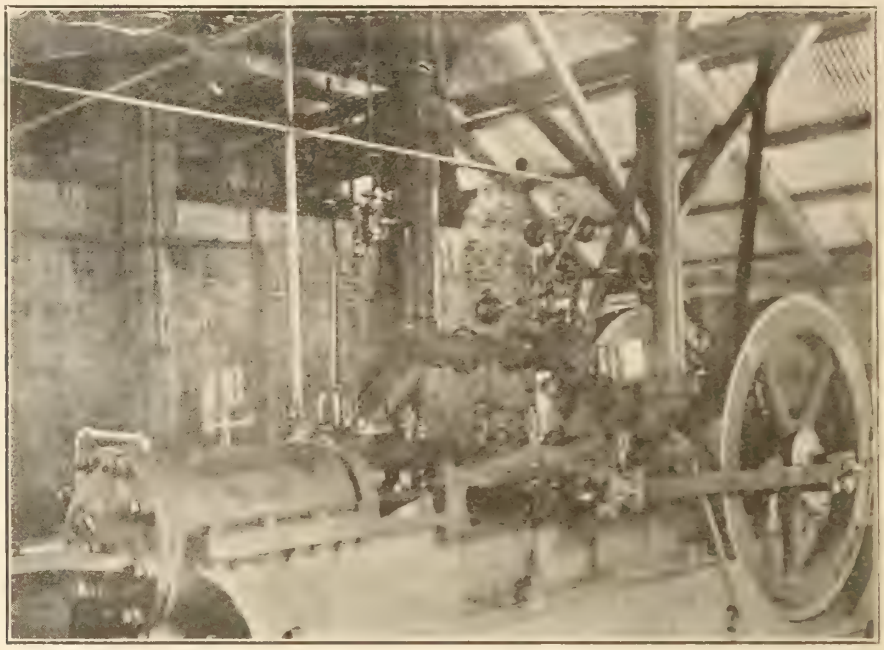
All these claims are situate around Ikeda Bay and take up the whole water front.

Shipments.—From November 1906 to the 1st of September 1908, 5,608 tons of ore have been shipped from the mine. Twenty-one hundred tons of this ore was first-class and averaged 12 per cent. in copper, $6 in gold and $4 in silver. The remaining 3,568 tons was second-class ore and averaged 6 per cent. in copper, $3 in gold and $2 in silver. This is taken from smelter returns. All this ore was shipped to the Tyee Copper Company's smelter at Ladysmith.

Equipment.—The mine is distant from tide-water 6,100 feet and is connected with a surface tramway of the same length. The cars run down by gravity to the ore bunkers at the water but have to be hauled back by horses as the elevation from the water to the lowest level is only about 200 feet. Later on I expect to equip this tramway with an electric motor.

Equipment.—There is a new Ingersoll air drill with large new boiler capable of running three drills.

Used by the Japanese miners as a bunk-house.



There is a large ore bunker at tide-water which has just been completed, capable of holding 1,000 tons of ore and the ore from this is loaded into the steamers almost automatically.

There are also two smaller ore bunkers at the mine, one of a capacity of 400 tons and the other of 100 tons.

The mine is well equiped with buildings, having a large bunk house and boarding house for the miners, engineer's house, superintendent's house, store house, assay office, stables, blacksmith shop, etc.

There are about 80 Japanese employed and 5 white men, the foreman and engineer, etc., being white men.

History.—This property was first discovered in May 1906 by the writer while he was engaged in the business of fishing for abelones. It is now a little over two years since the first pick was put in the ground and, considering the distance from supplies and the lack of facilities for getting things into the island, the advancement has been marvelous. The property has been shipping from nearly its infancy.

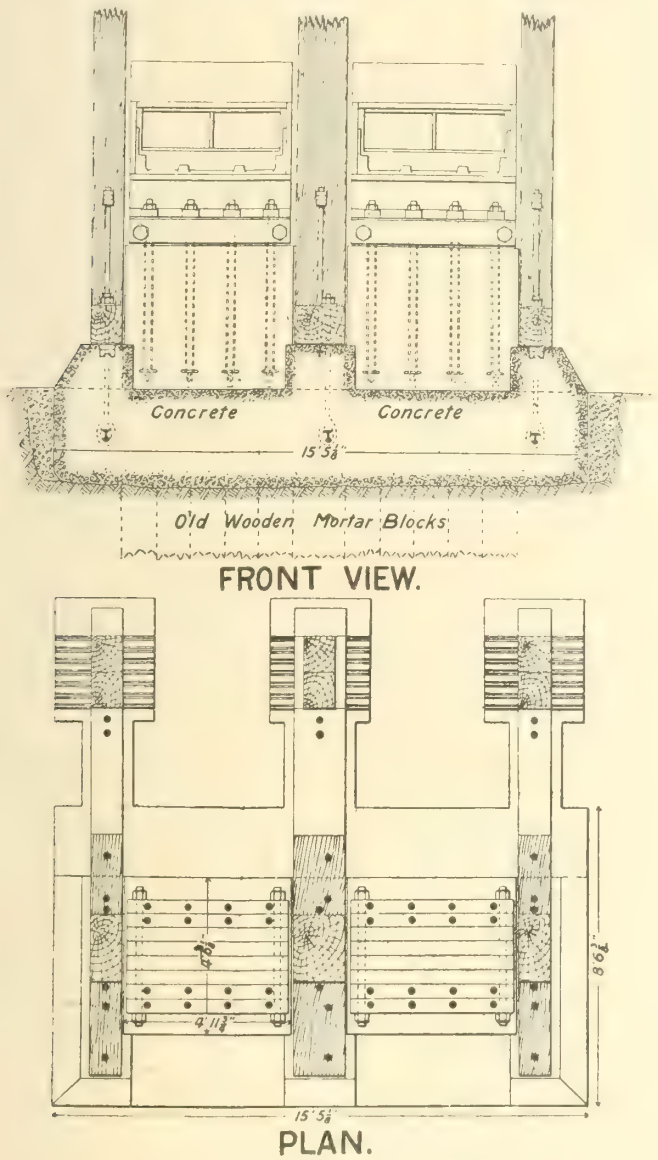
IKEDA MINE—ENGINE HOUSE

REINFORCED CONCRETE FOUNDATIONS FOR STAMP BATTERIES.

Paper read before the Institution of Mining and Metallurgy, by S. J. Truscott, Member, and John P. Fuller, Associate.

The wooden mortar blocks for the stamp batteries at Redjang, Lebong, Sumatra, which dated from the year 1898, having become rotten around the bolt holes and above ground generally, it became necessary to replace them. Being imbedded in much concrete, it would have been difficult to have drawn them, nor was this course necessary, because they were found to be in good condition below, and would not interfere with the stability of the concrete blocks it had been decided to raise over them. They were accordingly cut down sufficiently to allow a base blocks of concrete 850 mm. (2 ft. 9½ in.) in depth to be rested upon them, with its upper surface level with the ground. The block was built to accommodate ten stamps, and was 4700 mm. (15 ft. 5⅛ in.) long by 2600 mm. (8 ft. 6⅜ in.) wide, and, outside the limits of the wooden blocks, it rested upon a levelled surface of crushed stone beaten down upon the boulder clay which constituted the country rock; there was no question of putting the battery upon a more solid bedding.

At the back and on the same level the foundations for the central and two outside sills were hung out for a total length of 1830 mm. (6 ft.), each having at its end an expanded base, in which rails were embedded to distribute longitudinally the weight brought down by the ore-bin posts.



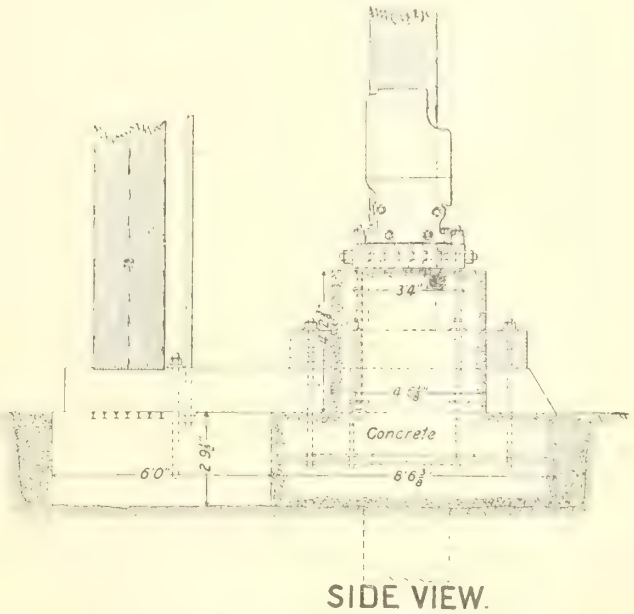
Into the main base block twelve 38 mm. (1½ in.) bolts, four under each king-post, were anchored on rails, to hold down the sills of those posts; and three other bolts of the same size were put down in the back foundations to secure the sills of the ore-bin posts.

It is pertinent here to give some description of the stamp and mortar box. The total weight of the falling stamp was 522 kg. (1150 lb.) and the number of drops was 96 per minute through 195 mm. (7¾ in.). The mortar box had, by reason of the difficulties of transport, to be sectionalised, the bottom being made up of seven cast iron cross sections having planed faces, drawn together by four longitudinal bolts of 45 mm. (1¾ in.) diam., with nuts recessed in the end sections. The upper parts of these boxes were of 13 mm. (½ in.) steel plate riveted together and to the bottom sections.

In order to relieve these longitudinal bolts of any undue strain which might come upon them by reason of irregularities of seating, each box was placed on an anvil block made up of longitudinal sections brought together by two transverse bolts of 57 mm. (2¼ in.) diam., the joints being planed and grooved, the bol-

tom of the box and the upper and lower surfaces of the anvil block were also planed.

The box had a width at its flanged base of 750 mm. (2 ft. 5½ in.), and, when using original wood blocks, six anvil sections were bolted together, making a total width of 760 mm. (2 ft. 5⅞ in.), the same as that of the blocks; one set of eight holding-down bolts then secured both the box and the anvil block. For the concrete it was decided to include eight sections in the anvil block to make a total width of 1015 mm. (3 ft. 4 in.), which would allow two sets of bolts, one of short bolts to hold the box on to the anvil block, and the other of long bolts to hold down the anvil block upon the con-



crete, which would then be given a width of 1375 mm. (4 ft. 6⅛ in.). The short bolts had countersunk heads which were winged to prevent rotation, but had there been convenience here they would have been so made that in case of breakage they could be withdrawn without the necessity of dismantling the box, which now exists, though the chance of breakage appears to be inconsiderable, special care having been taken to give them a true seating.

The usual design of concrete block has in transverse section a gradually increasing thickness towards the base, which design permits the holding-down bolts to be inclined, with their pocket holes removed from a position directly beneath the box, thus allowing the concrete there to be solid; another point of the usual design is that the bolts are laid in recesses from which they can be readily withdrawn in case of breakage.

In the case of the battery under description, such an increase of dimension towards the base would have encroached upon the freedom of the line shafting behind and have also thrust the pulp launder out of position in front, because there were no copper plates to carry the pulp well forward. The pulp dropped immediately into a launder set at a suitable inclination from both ends to the centre; the copper plates were kept in a separate house.

Further, the amount of metal in the flange at the base of the box and the shape of the anvil block did not allow of any departure from the vertical position for the bolts. With the material available, therefore, a straight up-and-down concrete block was determined upon.

Seeing that between the bottom of the box and the bolts in the concrete there were three intermediate bolts

to take up the jar of the blow, it was considered that those bolts were beyond reasonable chance of breakage. Their lower ends were therefore imbedded fast in the concrete, but in case a bolt should break it can still be withdrawn through the pipe casing in which it runs by first chipping away the concrete to free the cotter, when the vertical position of the bolt will allow it to be drawn up free of the box, whether front or back.

These bolts were 38 mm. (1½ in.) diam., but at the ends they were expanded to 42 mm. (1⅝ in.), to make good the loss of strength caused by the cotter hole or screw thread; they were also made long enough to allow the insertion of a deep cast-iron washer under the nut at the top, so that should a bolt break at the thread, or the thread become stripped, there would, upon removal of this washer, be space enough to cut another thread.

Such a mortar block for five stamps was 1520 mm. (4 ft. 11¾ in.) long, 1375 mm. (4 ft. 6⅛ in.) wide and 1280 mm. (4 ft. 2⅜ in.) deep; it rested upon the base block beneath to form with it one construction, of which the weakest plane was that where these two masses

met, across which plane a reinforcement was desirable, and was made by standing 25 iron rails so that one-third of their strength was in the base block below and two-thirds in the mortar block above, the average rail length being about 1500 mm. (4 ft. 11 in.). These rails were placed in five rows of five, and they were bound around and across with about 30 k. of twisted band-iron and 75 m. of barbed wire, the reinforcement being arranged in a manner prescribed for making concrete piles for general foundation work.

The crushed stone used in making the concrete was a hard andesite passed through a crusher set to a 38 mm. (1½ in.) ring. This material when screened over a bar screen set to 13 mm. (½ in.) spaces gave 43 per cent. coarse and 57 per cent. fine, the former containing 1 per cent. moisture and the latter 4 per cent. As this showed a good proportion of fines no such separation was made and the material was entered into the aggregate just as it was crushed.

The sand available was the well-washed residue from the cyanide works; this showed only about 10 per cent. remaining on a 40 mesh, so that in itself was not a good sand, being too fine and too regular in size, but taken together with the high proportion of fine material in the crushed stone it was suitable.

The cement used had the following grading, showing it to be rather coarse:—

			Remaining on	90	mesh	12.1 per cent.
Passing	90	mesh	"	150	"	3.3 "
"	150	"	"	200	"	17.2 "
"	200	"	"		"	67.4 "

It also showed alkalinity to the extent of 3.74 per cent., reckoned in terms of $Ca(HO)_2$, this presence of free lime being further indicated by a marked rise of temperature upon setting. But in spite of these departures from good character the tests to which it was submitted for soundness showed no signs of twisting, cracking, or distortion. In the actual process of working it took its initial set within half an hour and its hard set within three hours, thereby showing itself a convenient cement.

In order to arrive at the proper proportions of material to be used, determinations for voids were made with the crushed stone and the sand by loosely filling a measure having a capacity of ⅛ of a cub. m. without subsequent shaking, these being the conditions which would prevail at the actual mixing. The results showed the crushed stone to have 40 per cent. voids and the sand 47 per cent., these figures being higher than those generally recorded for such materials, which allow the measure to besettled by shaking, to reproduce the settlement caused during the transport of the measured material to the place of mixing. Allowing that the sand should fill the voids of the stone and the cement those of the sand, the proportions to make a good balance were determined as follows:—

Crushed stone	1000 parts.
Sand 40/100×1000	400 parts.
Cement 47/100×400=188, or say	200 parts.

or Cement 1. Sand 2. Crushed stone 5.

The actual amounts and proportions used for 10 stamps were as follows:

	Cement.	Sand.	Crushed Stone.	Proportion
	Cub. m.	Cub. m.	Cub. m.	
Back sill foundations	0·312	1·707	3·414	1 : 5 : 10
Bottom base block	0·500	1·500	4·000	1 : 3 : 8
Middle " "	0·625	1·250	3·125	1 : 2 : 5
Top " "	0·750	1·500	3·750	1 : 2 : 5
Bottom mortar block	0·500	1·000	2·000	1 : 2 : 4
Top " "	0·687	0·687	2·061	1 : 1 : 3
Shoulders for sills of king-posts.....	0·375	0·375	1·125	1 : 1 : 3
	3·749	8·019	19·475	1 : 2·1 : 5·2

The total volume of the loosely packed material before mixing was 31.243 cub. m., and the volume of the resultant constructions was 20.12 cub. m., or somewhat more than that of the crushed material alone.

The materials were very carefully hand-mixed, after which enough water was worked through the mixture to make a rather wet concrete, which was quickly taken and dumped into position into which it was further tamped. The work was not continued through the night but, when leaving it unfinished, the surface was roughened up, and on resuming next morning it was well sprinkled over with pure cement before the next lot was dumped on. The base block and other parts were formed up between boards, but the mortar blocks were more carefully shaped up in exact forms with interiors well soaped, and upon nearing the top, the concrete was added in smaller and smaller amounts which were carefully put into place before more was added, this care being to get a good surface free from any large pieces and not over-full. A cover was then put on and weighted down to remain over night.

Upon removal of the forms next morning, vapour rose off them, and they were perceptibly warm to the hand, the rise in actual temperature being about 20 degrees C., as determined by a thermometer, for which a hole was left in the top of a block.

The blocks were carefully washed down, and for a few days afterwards they were kept damp. Some small insignificant cracks appeared in the first blocks made, these being apparently due to contraction, and generally there was a slight sinking of about 1 mm. at the centre, but the outside dimensions were unaltered.

Beyond a good scrubbing down, very little further preparation was necessary; the surface was in every case good and true enough to allow the anvil block to be put on with only a layer of tarred blanket between, the mortar box above being seated upon a sheet of rubber.

The blocks were, of course, at once firm enough to allow the superstructure to be erected, and the stamps were allowed to drop one month afterwards, when each foundation showed itself to be satisfactory.

The cost for such foundations for ten stamps were as follows:—

	Fl.	£	s.	d.
5916 k. of cement, cost delivered	1395·36	116	5	7
75 m. of old steel rails.....	75.00	6	5	0
60 k. of band iron.....	7.20	0	12	0
150 k. of barbed wire.....	5.00	0	8	4
Wood, oil, carpenters' labour....	70.00	5	16	7
93 days coolie labor to mix, transport, and place concrete.....	93.00	7	15	0

	Fl.	£	s.	d.
6 days mason	12.00	1	0	0
6 days native overseer	15.00	1	5	0
4 days European overseer	32.00	2	13	4
Foreman's time	20.00	1	13	4
55 days' coolie labor bringing stone to crush	55.00	4	11	8
Labor, cutting rails, preparing reinforcements	15.00	1	5	0
	Fl. 1794.56	£149	10	10

From these figures it is obtained that 1 cub. m. of concrete cost fl. 89.19, or 7l. 8s. 7d., of which the cement alone fl. 69-33, or 5l. 17s. 6d.; or one cub. yd. would would take 7l. 15s. 0d.

Shortly before this work of concrete foundations was begun, thirty identical stamps, with identical mortars and anvil blocks as described, were erected and put to work on wooden blocks as part of the same battery, and the experience has been that the concrete blocks cost very considerably less both in money and in time. With these stamps on wood, a comparison with respect to crushing efficiency was made, however, from which it could not be said that the concrete foundations showed any decided superiority, as one lot of stamps appeared to do as well as the other. It was, however, noticeable that with the concrete the nuts and bolts did not so readily work themselves loose, a fact which will be mor enoticeable as the battery gets older. When, late,r the holding down bolts are drawn up into shrinking or rotting wood, or when the wood gives way to the strain on those bolts, then the cotter plates will get out of truth and bolts will be the more liable to break; the concrete gives freedom from this liability, and it may be expected that over their life those blocks will show a greater efficiency than will the wood ones.

With the wood foundations there are no mud sills as there are in the usual design for such batteries, but the streak sills are supported on masonry along their length with additional support in the middle upon posts which stand up from the concrete fundament of the blocks; this construction reduces to a minimum any springiness of these streak sills which the usual support upon mud sills allows. The king-post is also seated upon a stiffening sill which again reduces any possible vibration and provides a piece easy of renewal in case the seating of the king-post should wear or rot itself loose; this piece also occurs with the concrete foundations. Each king-post is held down by two 38 mm. (1½ in.) bolts on either side, which are held against the streak sill beneath, and which in their turn hold down a stiff bar piece which passes right through the post; during construction pocket holes were left in the masonry for convenience in inserting these bolts, which were afterwards filled up.

These notes are offered in the hope that they may be of service in other remote situations similar to that of the battery under consideration, where use has to be made of the material at hand. For new work in countries with good ordinary means of communication the design of concrete blocks as used in South Africa would be proper, to which some application of the principle of reinforcement might perhaps be added with advantage.

THE PREVENTION OF MINE EXPLOSIONS.

REPORT.

To the Honorable The Secretary of the Interior.

Sir,—In response to your request that we co-operate with the United States Geological Survey in the inauguration of its investigations looking to the prevention of mine explosions, and that we submit for the consideration of those connected with the coal-mining industry in the United States such recommendations as experience in our own countries and observation among American coal mines indicates may be useful in providing for greater safety, we beg to submit the recommendations given below.

Since coming to the United States, we have given careful attention to and approve the investigations in relation to this subject begun by the Geological Survey. We have visited typical mines in the more important coal fields of the United States, and have discussed the mining problems with many coal operators, miners, and state inspectors.

To be effective, investigations for the benefit of mining must be continuous. The opening up of new mines, the deepening of old mines, the meeting with new conditions, the changing of explosives, and the inauguration of new processes and methods will call for continuous investigations, to be followed by continuous educational work.

Our investigations and recommendations relate primarily to questions of safety in mining; but in this connection we have been greatly impressed with another closely associated phase of the industry, viz., the large and permanent loss of coal in mining operations in many portions of the United States. This is a serious, permanent, and national loss. It seems to be a natural outcome of the ease with which coal has been mined in the United States and the enormously rapid growth of the industry.

The active competition among the operators and the constant resulting effort to produce cheaper coal has often naturally led to the mining of only that part of the coal which could be brought to the surface most easily and cheaply, leaving underground, in such conditions as to be permanently lost, a considerable percentage of the total possible product. Certainly much of this loss can be prevented through the introduction of more efficient mining methods, such as the long-wall system, more or less modified, the flushing method. (See "II," 7, p. 10.)

In the preparation of these recommendations we have recognized fully the great differences between the mining conditions in Europe and those in America, where the industry has developed so rapidly that thorough organization has not yet been possible; where a large percentage of the men entering the mine are unfamiliar either with mining methods or the English language; and where the price of coal at the mine is less than half that in Europe. Nevertheless, we believe that these recommendations will be found useful in the

further development of the American coal-mining industry for safety and efficiency. The cordial reception everywhere accorded us leads us to believe that these recommendations will be received by the operators and miners in the same spirit of good will as that in which they have been prepared. But the success of this movement for greater safety and efficiency will depend upon the hearty and patient co-operation of the operators and the miners, working together for the accomplishment of this purpose.

RECOMMENDATIONS.

A. Selecting the Explosives to be Used.

(1) We recommend that the Government of the United States examine the explosives now and hereafter used in mining, with a view to eliminating the more dangerous explosives and to improving and standardizing such explosives as may be considered most suitable for such use, these to be designated by the Government "permissible explosives."

The term "permissible explosives" is suggested for the reason that no explosives are entirely safe, and all of them develop flame when ignited; and we advise therefore against the use in the United States of the terms "safety explosives" or "flameless explosives," as these terms may be misunderstood and this misunderstanding may endanger life.

(2) We recommend that the operators and miners of coal use only such explosives as are included in a list of "permissible explosives," when the same has been published by the Government, in all mines where there is risk of igniting either dust or gas, selecting that one which their own experience indicates can be used to the best advantage under local conditions.

(3) We also recommend that investigations be conducted to determine the amount of charge of such "permissible explosives" which may be used to the best advantage under different conditions with a view to reducing danger to the minimum.

B. Carrying the Explosives into the Mines.

(1) All explosives should be made into cartridges and placed in closed receptacles before being carried into the mine, and the quantity carried into the mine during one day by any miner should be limited as nearly as practicable to the quantity needed by him for use during that day. Handling loose explosives and making them into cartridges by an open light in the mine should be prevented.

(2) Detonators or caps should be handled with great care, and should be carried only by a limited number of responsible persons.

C. Use of Explosives in the Mine.

(1) Shooting in or off the solid should not be practiced.

(2) The depth of the shot hole should be less by at least 6 inches than the depth of the cutting or mining. The use of very deep shot holes should be avoided as unnecessarily dangerous.

(3) The overcharging of shots (the use of a larger charge than is required to do the work satisfactorily) should also be avoided as unnecessary and dangerous. The proper standardization of explosives used in coal mining will greatly facilitate the carrying out of this recommendation. (See also "A," 1, p. 7.)

(4) Shots should never be tamped with fine coal or material containing coal. Clay or other suitable material should be supplied and used for this purpose.

(5) The firing of two or more shots in one working place, except simultaneously by electricity, should not be allowed until a sufficient interval has elapsed between the firings to permit an examination of the working place in order to see whether any cause of danger has arisen.

(6) Before a shot is fired the fine coal should be removed from the working place, as far as practicable, and the coal dust on the floor, sides, and roof, for a distance of at least 20 yards from the place where the shot is to be fired, should be thoroughly wet, unless it has been demonstrated that the dust in the mine is not inflammable. (See also "E," 1, p. 9.)

(7) If gas is known to occur in the mine, no shot should be fired until, in addition to the watering, an examination made immediately preceding the time for firing, by a competent person, using a lamp which will easily detect 2 per cent. of gas, has shown the absence of that amount of gas from all spaces within 20 yards of the point where the shot is to be fired.

(8) Believing that such will be one of the greatest advances which can be made in safeguarding the lives of the miners, we recommend the adoption of a system of electric shot firing, in all mines where practicable, by which all shots in the mine, or in each ventilation district of the mine, may be fired simulanteously, at a time when all miners and other employees are out of the mine.

D. Keeping the Mine Roadways Clean.

(1) The roadways of the mines should be kept as free as possible from loose coal which may be ground into dust and of rubbish in which such dust may accumulate, in order to facilitate the removal and wetting of the dust.

E. Wetting the Coal Dust.

(1) In all coal mines where explosives are used it is desirable, and in all mines containing gas it is highly important, that the dust on the walls, timbers, and floors of the working places and roadways should be kept continually wet prior to and during the work in the mine. If, however, conditions of roof or lack of water render this general watering impracticable, at least the dust within 20 yards of each shot should be wet before each firing, and other precautions against explosions should be practiced with unusual care.

It is our opinion that a system of watering which occasionally sprinkles the floor only and leaves dry the dust on the walls and timbers of the roadways is useless and is also dangerous in that it may generate an unwarranted feeling of security against an explosion.

F. Special Precautions for Mines Containing Gas.

(1) In any mine where as much as 2 per cent. of gas can be detected by suitable method only locked safety lamps of an approved type should be used so long as such condition exists or is likely to recur.

All safety lamps should be maintained in good condition, cleaned, filled, kept in a special room at the surface, and carefully examined both when delivered to the miner and when returned by him at the close of each day's work. A defective safety lamp is especially dangerous because of the false feeling of security it engenders.

In the filling of lamps with benzine or other low-flash oils, which should always be done at the surface, special precautions against fire or explosions should be taken.

G. Use of Electricity.

(1) Electricity in mining operations offers so many advantages, and has been so generally adopted, that no reasonable objection can be made to its use under proper restrictions. The electrical equipment, however, should be installed, maintained, and operated with great care, and so safeguarded as to minimize danger from fire or shock. The fact that the effectiveness of some insulating materials is soon destroyed in most mines should not be lost sight of.

We recommend the following precautions: For distribution underground the voltage should not exceed 650 direct current or 500 alternating current, these voltages being intended for transmission to machinery operating at 500 volts direct current and 440 volts alternating current, respectively. Even lower voltages are preferable. The trolley wires should be installed in such manner as to render shocks least likely; that is, placed either high enough to be beyond easy reach or to one side of the track and properly protected.

Where current at a potential of more than 650 volts is employed for transmission underground, it should be transmitted by means of a completely insulated cable; and where a lead or armored covering is used, such covering should be grounded.

In all mines having electric installation special precautions should be taken against the setting on fire of coal and timber. Inclosed fuses of cut-outs are recommended, and each branch heading should be so arranged that the current may be cut off when necessary.

No live electric wire should be permitted in that part of any mine in which gas is found to the amount of 2 per cent.

In all mines producing gas in dangerous quantities, as indicated by a safety lamp which will detect 2 per cent. of gas, the working places should be examined for gas by a qualified man, using such a lamp, immediately before any electric machine is taken or operated there.

H. Precautions Against Miscellaneous Accidents.

(1) In all new construction, shaft lining and superstructures about the entrance of the shaft (or slopes or drifts) should be built as far as practicable of noncombustible materials.

About the entrances to mines, every possible precaution should be taken to prevent fires or the injury of the equipment for ventilation and haulage. Ventilating fans should be placed to one side of the mine opening, and hinged doors or light timbering should render easy the escape of the explosive force in direct line of the shaft of slope.

Proper precautions should be taken for immediately preventing the entrance into the mine of heat and gases and for facilitating the escape of the men in case of surface or shaft fires.

(2) The surface equipment for handling the coal should be so arranged as to prevent coal dust entering into the mine shaft.

(3) In all new mines, and in all old mines as far as practicable, suitable man roads should be provided for the men separate from the main haulage roads.

(4) In connection with the system of venilation it is recommended that in the more frequented roads connecting the intake with the return air centres, two doors be provided, these doors to be placed ot such a distance apart that while one is open the other is closed.

(5) In view of the large number of accidents from falls of coal or roof, under the existing practice with single props, more attention should be given to the introduction in mines where the roof is bad of better systems of timbering, such as have been long in use with economy and safety in many well managed mines.

(6) In undercutting coal by hand, the premature fall of the coal should be prevented by sprags or other suitable supports.

(7) We believe that the difficulties and dangers encountered in the working of coal seams which are thick and steeply pitching, or of which the coal is highly inflammable in character or subject to firing from spontaneous combustion, and in mines where the subsidence of the surface must be avoided, may be successfully and economically overcome in many cases through the adoption of the flushing system of mining—that is, the filling with sand or other similar materials of the space from which the coal is removed. The system originated in the United States and is now successfully practiced in portions of Germany, Austria, Belgium, and France.

I. Mine Supervision and Inspection.

(1) We can not too strongly emphasize the fact that thorough discipline about the mine is absolutely essential to safety, and that thorough discipline can be brought about only through the hearty co-operation of the operators, the miners, and the State.

(2) We are of the opinion that the responsibility for safety in the mine should primarily rest with some person, such as the manager or superintendent, clothed with full authority; and that such person can greatly facilitate the attainment of safety through the employment of a sufficient number of foremen, and also of one or more inspectors whose special duty it shall be to see that the regulations are strictly enforced.

(3) The State can not exercise too much care concerning the experience, technical training, and selection of its inspectors. Their positions should be made independent of all considerations other than that of efficiency; and their continuance in the service should be coexistent with good behavior and proper discharge of official duty.

J. Training for Mine Foremen, Inspectors, Etc.

We are of the opinion that the cause of both safety and efficiency in coal mining in the United States would be greatly aided through the establishment and maintenance in the different coal regions of special schools for the training of fire bosses, mine foremen, superintendents, and inspectors. The instruction in such schools should be practical rather than theoretical.

The work of these schools would supplement most effectively that of the colleges already established in many parts of the country for the more thorough training of mining engineers.

Respectfully submitted.

VICTOR WATTEYNE.
CARL MEISSNER.
ARTHUR DESBOROUGH.

THE NORTON HILL COLLIERY EXPLOSION.

The report of H. M. Inspector of Mines Joseph S. Martin on the Norton Hill Colliery explosion indicates that the explosion was due to the presence of coal dust. No perceptible amount of fire-damp was present. The explosion resulted in the death of ten persons. The report lays stress upon the necessity of attacking the coal-dust problem and of watering dusty sections. The conclusion is reached that if there had been even a small percentage of gas in the air the explosion would have been much more violent.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

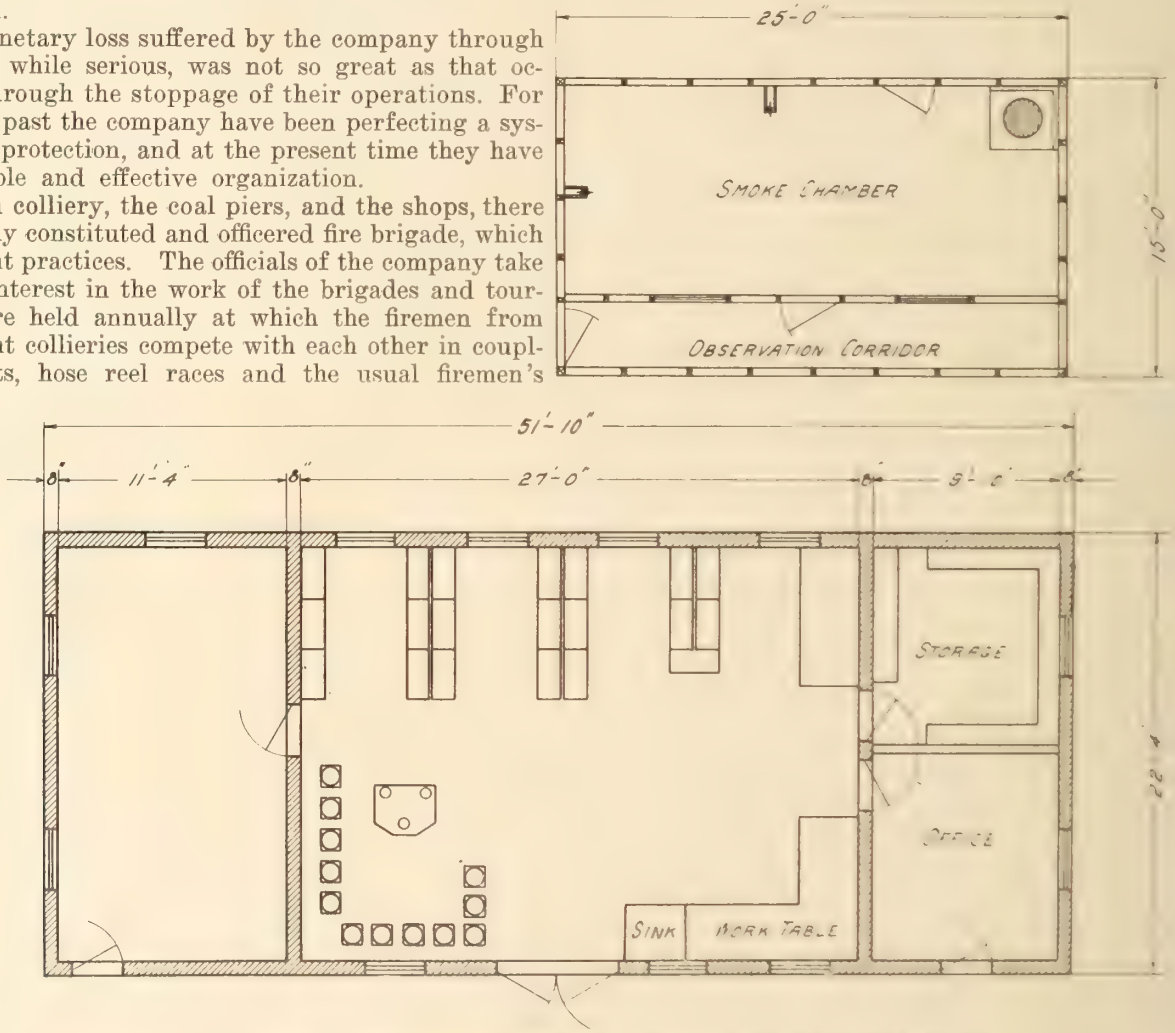
By F. W. Gray.

(Continued from last issue.)

The Fire Fighting Organization and Equipment.

The Dominion Coal Co. have in the past suffered severe losses through fire, both above and below ground. In 1903 a fire occurred in Dominion No. 1 mine, and in 1906 a fire broke out in the pit bottom of the Hub Colliery. In both cases the mine had to be flooded before the fire could be extinguished. At the Hub the surface erections were all destroyed. In October, 1906, the old bankhead at Reserve was completely destroyed by fire, and in 1908 the wash plant at Port Morien was burnt down.

The monetary loss suffered by the company through these fires, while serious, was not so great as that occasioned through the stoppage of their operations. For some years past the company have been perfecting a system of fire protection, and at the present time they have an admirable and effective organization.



At each colliery, the coal piers, and the shops, there is a properly constituted and officered fire brigade, which has frequent practices. The officials of the company take an active interest in the work of the brigades and tournaments are held annually at which the firemen from the different collieries compete with each other in coupling contests, hose reel races and the usual firemen's sports. Each colliery also has a building, generally known as the firemen's hall, which is set apart for the social use of the firemen in the evenings. In this building is also stored the fire-fighting equipment, which consists of fire hose, reels, rubber boots, rubber coats and sou'westers.

Each colliery has a system of fire hydrants, and standpipes are placed throughout the bankheads and other large wooden structures, with coiled fire hose coupled up in readiness for instant use. The buildings are all supplied with chemical fire extinguishers, hung up in convenient situations.

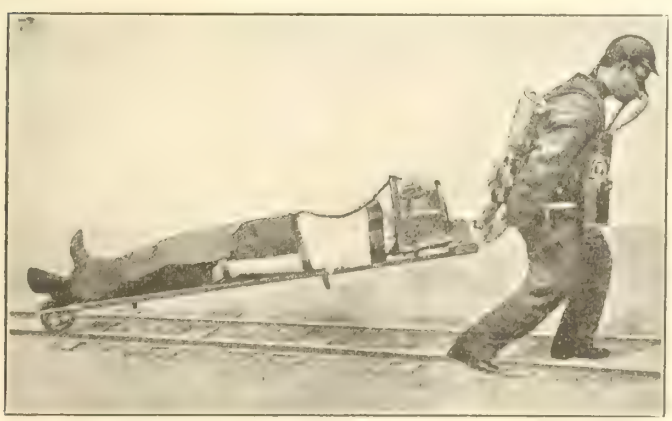
Particular attention is paid to the matter of cotton-waste and oil. Drip pans are placed beneath all lubricating bearings and shafting in positions where the oil drips, keeping the wooden erections from becoming oil soaked and thus dangerous as a fire risk. Cast iron receptacles, sufficiently heavy not to be easily moved about or overturned, are provided to hold the waste. These receptacles contain two compartments, one to contain the clean waste and the other for the oily waste. Loose rubbish and oily waste are not allowed to be promiscuously thrown around.

A separate building at each colliery is provided for the storage and distribution of oil. These buildings are placed in an isolated position, and buckets of dried sand are always kept near at hand.

Particular care is taken to keep live steam pipes from coming into contact with wooden structures, and where

A—Plan of Central Rescue Station, Showing Apparatus Room, Emergency Hospital and Smoke Chamber.

Draeger Apparatus—Helmet Type.



steam pipes pass through wooden partitions the wood is protected by the regulation bushing. Wherever high tension electrical current passes near timber structures instructions are given that dried sand is to be kept in a handy situation.

Similar precautions are taken underground. Where compressed air is carried into the workings arrangements are made to allow the discharge of the mine pump or some other adequate water supply to be turned into the air pipes, which thus become water mains extending into the interior of the mine. The fire stations are plainly marked, and the underground firemen, known as the Rescue Corps, are expected to know the position of these mains and connections in the same way that the surface fire brigade know the position of the colliery hydrants. Plans are kept on file showing the position of all the air and water connections both above and below ground.

In collieries where the workings are dusty, periodical sprinkling takes place, and in some instances the dust is swept up and taken out of the mine.

As on the surface, all the underground engine houses are provided with chemical fire extinguishers. Special electrical rules and warnings are placed in all electrical engine and pump houses.

One of the most interesting features of the company's scheme of fire protection is the Central Rescue Station, near No. 2 colliery. This is a substantial brick building, with concrete floor, containing four rooms. (See plan accompanying "A").

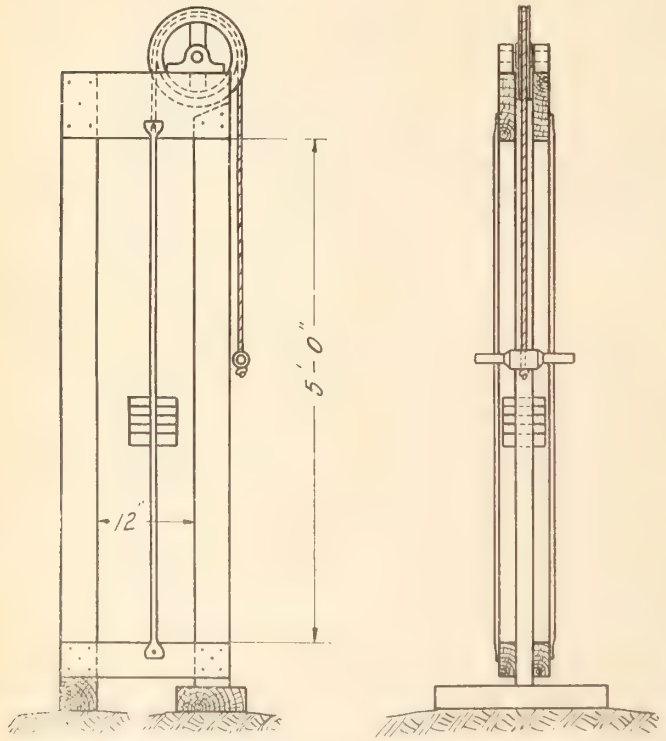
Method of transporting injured or unconscious man on oxygen stretcher.

The main room of the building contains a series of wooden cabinets (photos 1 to 5) on which are stored the breathing apparatus, which form the equipment of the station. These are all of the Draeger type, which consists briefly of a helmet, two flasks of compressed oxygen and two potash regenerator cartridges. The mode of operation may be seen from the accompanying diagram, and is shortly as follows:

The oxygen is contained in the twin cylinders at a pressure of 225 atmospheres. When released by turning the valve it passes out through a reducing valve at a pressure of 1-5 atmospheres through a side tube and into the air space of the helmet, emerging immediately in front of the mouth of the wearer. The helmet connects with two bags lying on the chest, one for the oxygenized air supply and the other for the expired air. These bags serve merely as a reservoir and to equalize the circulation. The expired air passes through a tube on the opposite side of the helmet and is passed through the re-

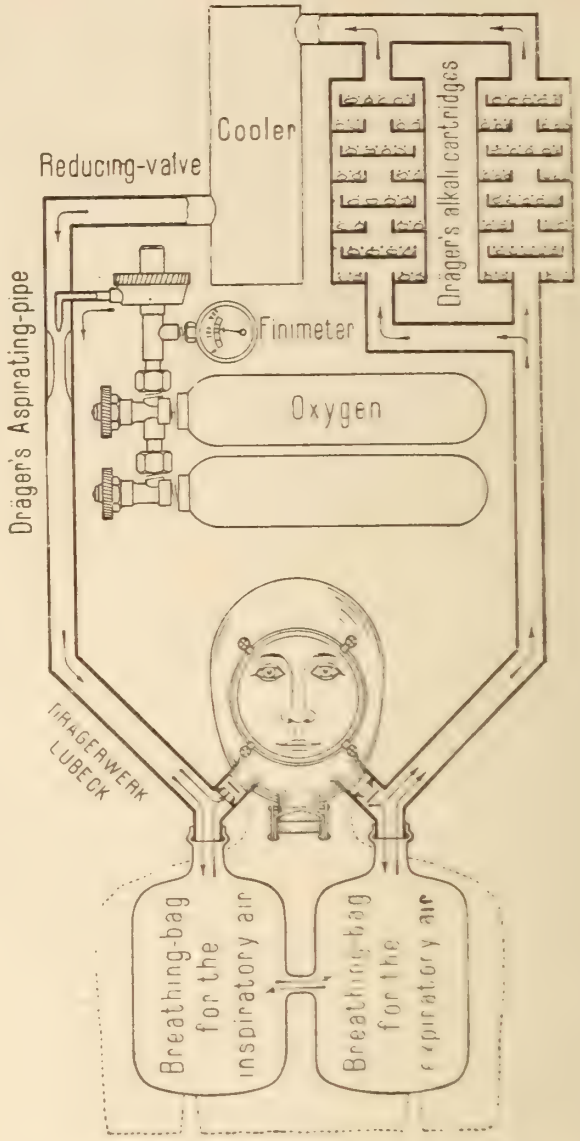
Draeger Apparatus—Mouth-Breathing Type.

generator cartridges. These consist of tin cylinders containing layers of finely granulated potash or shelve so arranged as to present the greatest possible superficial area of absorbing surface. The potash takes up the carbon di-oxide of the expired breath, and the purified air passes through a cooler, finally joining the main oxygen stream issuing from the cylinder. The process is continuous, and the apparatus is designed to enable the wearer to work for two hours quite independently of the nature of the outside atmosphere.



The most characteristic part of the Draeger apparatus is the helmet, which is a brass mask covering the entire face and the crown of the head, but leaving the ears free. Inside it has a collapsible rubber lining which may be inflated and deflated in the same manner as the tire of a bicycle. By inflating the pneumatic

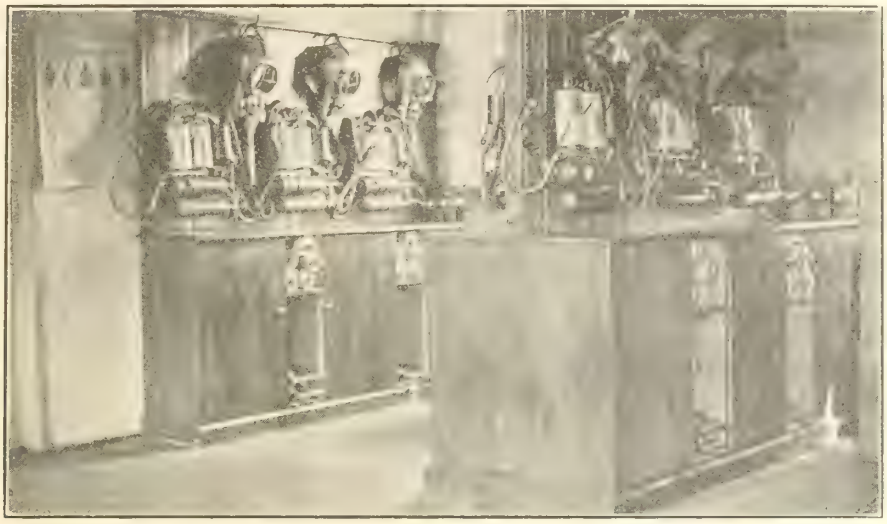
lining the helmet can be made to fit exactly into all the crevices and curves of the facial outline, and entirely exclude the outside atmosphere. The front of the helmet consists of a large circular pane of mica which affords unobstructed vision. The entire apparatus fully charged weighs about 38 pounds.



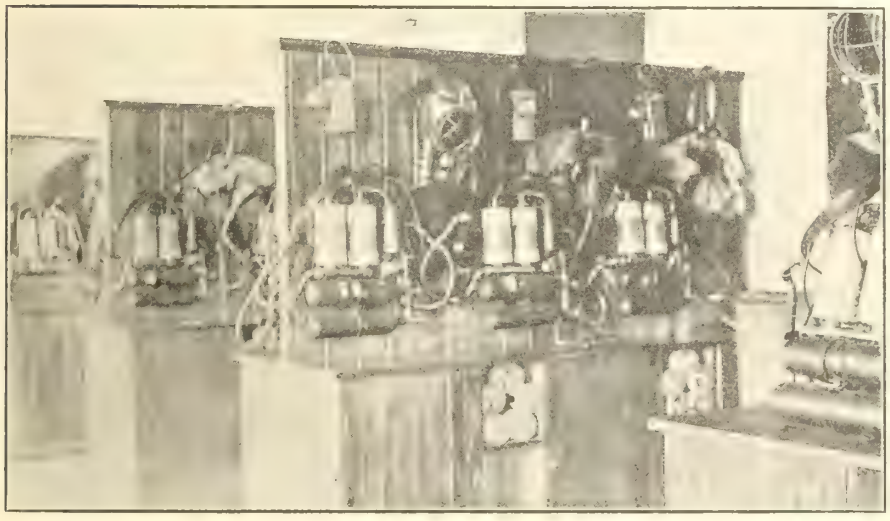
The station is equipped with 20 apparatus and 15 auxiliary sets are kept at the collieries. The oxygen supply, which is never allowed to fall below 1,000 feet, is kept in the main room in crucible steel cylinders, each holding 100 cubic feet at a pressure of 80 atmospheres. The small cylinders of the apparatus are charged by a refill pump, which compresses the oxygen from 80 atm. to 225 atm., the pressure for which the apparatus is designed. Electric hand lamps, corresponding in number to the apparatus, are kept on hand in the station, already charged for immediate use. The station has a small independent charging arrangement for the lamps, the current being obtained from the colliery wires. In addition to the Draeger apparatus the station has a Konig Smoke Helmet. This is a leather and mica hood connected by hose with a bellows to pump fresh air to the wearer. The hood has a mouthpiece, and a receiver is held by the man operating the bellows, enabling them to speak to each other. This device is useful for work in foul air at a short distance from fresh air, such as building stoppings. It was bought before the station was erected.

The station is connected by telephone, on its own special circuit, with all the collieries, and by means of an extension instrument is connected with the instructor's residence, close by the station. The instructor keeps in constant touch with the central of the coal company's private telephone system.

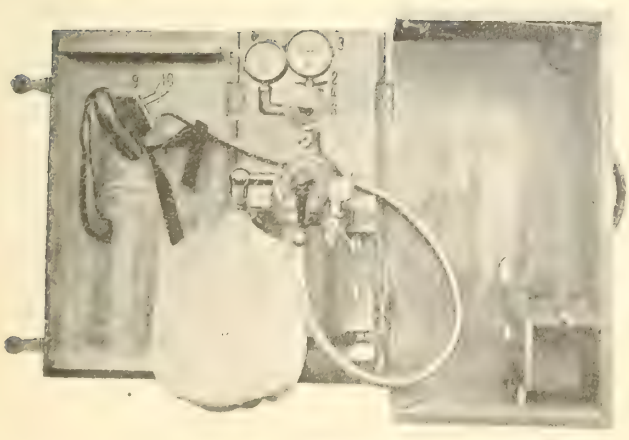
Adjoining the station is the practice smoke chamber. This is a rough-wooden shed, consisting of an observation corridor divided from the main building by a partition with glass windows.



Weight and Pulley Exerciser used in the Smoke Chamber.



The smoke chamber proper has no windows, and has a fire grate in one corner on which materials are burnt to make a stifling smoke. There are two weight lifting machines for exercising, consisting of a rope passing over a pulley attached to a weight of 45 lbs. Men training in the use of the breathing apparatus enter the smoke wearing the apparatus and carrying electric lamps. Each man does a certain amount of work on the exercisers, and they thereby become acquainted with the working of the apparatus, and its effect upon them individually. The instructor is able to gauge the effectiveness of a man, as shown by the number of times he can lift the weight, and his behavior under the physical strain, and is able also to judge of the suitability of each man for the work. This training and testing process is quite necessary, as not all men are fitted to wear the apparatus or to perform the exhausting work which in case of emergency they will be called upon to do.



Among the equipment of the station is a "Dr. Bratt" resuscitator. This is a device for inducing artificial respiration and administering oxygen. It consists of a flask of oxygen connected by the tube with a mask for the mouth and nostrils. By moving a handle to and fro the lungs of an unconscious person may be inflated and deflated as in natural breathing. The device

is of special value for reviving men who have been "gassed," particularly those suffering from the carbon-monoxide poisoning which so frequently kills the survivors of a mine explosion. The station has also a auxiliary apparatus are kept at some of the outlying collieries. These are intended for use by the colliery Rescue Corps pending the arrival of a detachment from the Central Station, if this should be found necessary.

Another corner of Rescue Station, showing refill pump, portion of exercising device and 6 oxygen cylinders.

similar arrangement mounted on a special stretcher fitted with a deep grooved wheel which can be run along the mine rails, thus facilitating transport. By means of this device, in conjunction with the Draeger apparatus, it will be possible for a party of rescuers to penetrate into deadly gases, to revive the unconscious survivors and carry them to the outer air.

One end of the Rescue Station is fitted up as an emergency hospital and dressing room. It contains a wash-basin, spring couch, table and rubber sheet. First aid requisites, blankets and stimulants are kept on hand.

In addition to the apparatus in the Central Station,

The whistle signals at the different collieries, which at one time varied, have now been standardized. The ordinary whistle is used for the "work" and "no work" signals, and siren whistles only are used for fire alarm purposes. The sirens at the collieries are to be distinguished from each other by their varying pitch. The following is the standard code of signals now in use:

Fire in the mine—2 toots and a pause, repeated.

Fire on the surface, or in colliery buildings—3 toots and a pause, repeated.

Fire in the dwellings—One blast of siren, with a number of short blasts to indicate Ward number.

ONE OF THE RESCUE CORPS OF THE DOMINION COAL COMPANY. BRICK BUILDING IS ONE END OF STATION.

Each colliery has either two or three Rescue Corps, consisting of men who are resident at the colliery and acquainted with the workings. These men are chosen because of their knowledge of the underground workings, ventilation and position of air roads, pipe lines and connections, but they are first of all passed by the instructor as being suitable. The names of the men composing the corps and the periods for which they are detailed for duty are posted in the Firemen's Hall, near the apparatus. As far as possible the corps are so arranged that the trained men at one colliery shall not all be underground at the same time.

The instructor makes periodical rounds and exchanges the colliery apparatus for others that he brings from the Central Station. This is done so that the apparatus may always be in good working order.

Up to the present time (December, 1908) there has been no call upon the Central Station from the company's own mines, but a detachment of 25 men in charge of the Superintendent of No. 2 District and the Instructor went to Sydney Mines on the 11th of September, 1908, and were of considerable assistance in extinguishing a fire in Sydney No. 1 Mine, which was burning at a point 2¼ miles from the pit bottom. On this occasion both the training of the men and the effectiveness of the apparatus was put to the severest test with extremely gratifying results.

At the end of 1908 the Central Rescue Station of the Dominion Coal Company was the only one of its kind on the American continent, and it is superior in the extent of its equipment and the number of trained men to any station outside of Germany or Austria.

THE SEPARATION OF METALLIC ORES BY JIGGING.

Read before the Institution of Mining and Metallurgy, by Arthur Taylor, Member.

Where ores are carefully classified, the lowest size that can be jigged satisfactorily is above a 16-mesh sieve, and the writer thinks he is right in saying that jigging is not often applied even to such a fine size. When less careful classification is resorted to, and fine stuff is allowed to pass over a jig with the coarser, much ore is lost.

In the ordinary mechanical jig a speed of 300 rev. per minute is about the maximum, with a minimum stroke of, say, 2 mm. to 4 mm.; and even with this, there is much strain on the parts and corresponding wear and tear. The regular beat of the plunger causes too great a rush of water, and that carries upwards the minute particles of ore.

In the opinion of the writer, the finest slimes that can be treated by any mechanical means can be treated with excellent results in jigs, more conveniently, and with less working expenses and less cost in plant than by any other apparatus, provided the jigs are of a suitable construction.

In the first place the pulsating action must be reduced to a minimum, and the rapidity of the stroke increased up to the point of a simple vibration, and the supply of water should be regulated to be just sufficient to keep the matter in a state of semi-suspension, like a quicksand; enough to prevent packing and to allow of the shifting of the particles one on the other, but not enough to lift them and allow the finer particles to be carried up by the current.

A constant movement is indispensable to prevent the establishment of uneven currents, to produce an even distribution of the minerals and the water, as well as to provide the interchange of position of the particles one on the other, quite distinct from the regular rise and fall of the particles produced by the even beat of a plunger. Also a most important point is that in the case of fine slimes the vibration certainly promotes the more rapid settling from the water of the suspended matter. This diminishes the loss in the case of impalpable slimes flowing over jigs.

The writer has met the requirements of the case by a complete modification in the form of apparatus and the substitution of a vibrator for the plunger, thus suppressing the portion of the hutch in which the plunger works. The vibrator is fixed to the hutch which carries the screen; or it can be attached to the screen by arranging this so as to have free motion in the hutch.

The action of the vibrator depends on the fact that a rapidly revolving mass tends to rotate round its centre of gravity, and if the centre of rotation is uncontrolled it will coincide with the centre of gravity.

The vibrator designed by the writer is as follows: A shaft provided with weights in the form of discs or flywheels attached, and constructed in such a manner that the journals of the shaft do not coincide with the centre of gravity of the mass. On a rapid rotation being imparted to the whole, the tendency of the mass to rotate on its centre of gravity transmits the vibration through the journals and their bearings to the supports, or connecting rods, which communicate it to the required point.

The details of construction will be seen on the accompanying illustration, Fig. 1, which shows the vibrator more or less in diagrammatic form.

The steel vibrator shaft A has eccentric journals B at each end (the centre of the journal being 2 mm. from the centre of the shaft). On the shaft are firmly keyed two collars or sleeves C provided with shoulders, and on these sleeves are fixed the eccentric discs or flywheels D, the centres of which are 2 mm. from the true centres of the discs. The position of the disc in relation to the centre of the journals is regulated by turning the disc on the collar, to which it can be firmly fixed by means of bolts E. The collar is pierced by several holes, pairs of which correspond with the two on the disc in such a way that any desired amount of eccentricity can be given.

The holes are numbered so as to insure correct setting. At zero the discs are practically concentric with the journals of the shaft, at No. 4 they have the maximum eccentricity of 4 mm. In the centre of the shaft is fixed the driving pulley F, the boss of which is also eccentric and provided with several keyways in order that it can be set in such a position that it will rotate as nearly as possible concentrically.

The vibrator is supported on two spring connecting rods H. They are forged out of one piece of spring steel and provided with metal bushings I. The two bushings are practically the only parts in the whole apparatus subject to any wear, and they will last several months if made of ordinary white metal.

The connecting rods are firmly bolted to crossbars or bridge pieces K fixed to the sides of the hutch L. The method of attachment and the relative position of the vibrator and hutch are shown in Figs. 2, 3, and 4.

The hutch L is a hopper-shaped box from 60 to 75 cm. long and 35 to 40 cm. wide. The upper part is parallel and built of 3 or 4 mm. steel plate. The lower part, hopper-shaped, is of the same material but thinner. The two large sides of the hopper are rendered flexible by the insertion of sheets of india-rubber or strong canvas, M, to allow of the freer vibration or pulsation of the hutch by liberating it from the inertia of the mass of water. A trial was made of a hopper constructed of very thin steel or phosphor-bronze plates, but, although they worked satisfactorily, the metal could not stand the strain, and at the end of a few weeks the plates would crack or break away from the thickness of the bed above the grating. In some cases, such as when there are more than two jigs in a set, or in dealing with very firm slimes, it has been found advantageous to draw off part of the water coming off the jig apart from the material under treatment. If this was not done, the increased flow of water over the lower jigs in the set would carry the ore away. The lip can therefore be made in two stages. Above the lower one are placed a series of holes through which the material escapes with a certain quantity of water and flows into the next jig, while the superabundant water flows over the top lip and is conducted away to waste. This arrangement also has the advantage of checking the flow and leaving a certain depth of water on the bed.

The wire gauze of the screen should be far coarser than the material under treatment, say, 10 mesh for stuff passed through a 14-mesh sieve, and never less than 50, even for stuff that will pass through a 250 mesh, that is to say, the finest slimes. On the gauze screen is placed a thin bed, from 25 to 50 mm. deep, of lead shot, "small dust" for the finest ores, up to Nos. 6 or 8 for the coarser sizes. On the shot is placed the

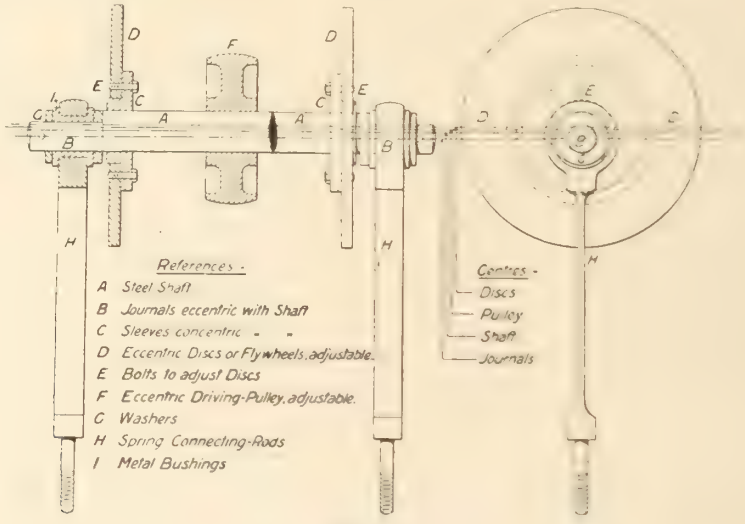

Fig. 1

the rivets. At the bottom of the hopper is a valve N for drawing off the concentrates.

On the sides of the hutch are four rectangular lugs or supports O, on which the whole apparatus is hung, on two parallel beams, P. Four bolts or spindles are fixed in the beams, passing through holes in the lugs to keep the whole in place, the lugs being supported by stiff spiral steel or india-rubber springs, both above and below. In Fig. 2 are shown the alternative fittings with spiral and india-rubber springs. On the spindles are nuts to tighten or loosen the springs as may be required for the proper working.

Inside the hutch at the top of the hopper is a ledge on which is supported a cast steel grating R, which carries the wire gauze, with another similar grating above to keep it in place, all being firmly fixed with hardwood wedges and iron lugs on the inside of the hutch. Around the grating is packed with slips of soft wood or cord to prevent leakage.

At one end of the hopper and under the grating is fixed a short pipe S, connected by a flexible tube to a tap, for the introduction of water.

An overflow lip T is placed at one end of the hutch, arranged so that it can be raised or lowered to regulate true bed on which the separation takes place. The chief use of the shot is to keep the bed off the screen, as it would otherwise get choked, and it allows of a much coarser gauze being used.

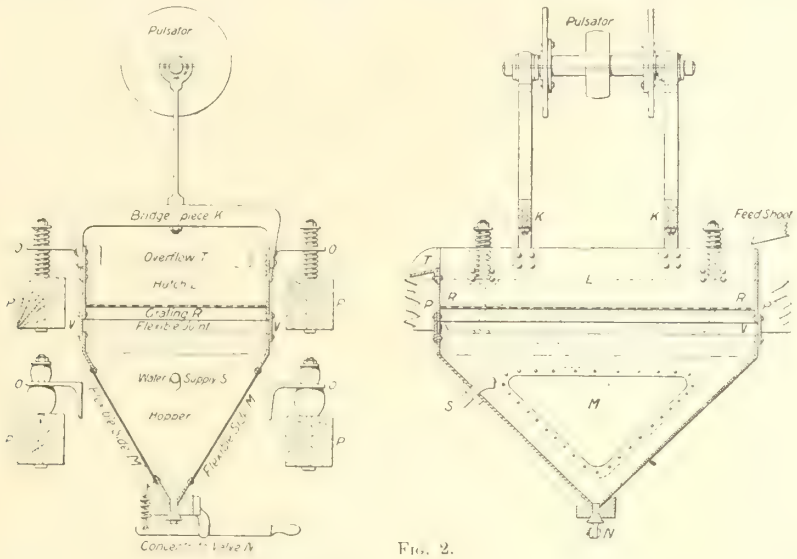
The construction of these jigs is entirely the same for coarse or fine ore, and all parts should be interchangeable, the only exception being that the discs are made heavier for the coarser ores, the weights varying from 2½ k. to 5 k., the lighter ones being driven at about 1,500 rev. a minute, with perhaps 1 mm. eccentricity, the heavier ones at 500 rev. with the maximum of 4 mm. eccentricity. Of course, the length of stroke is far less than the amount of the eccentricity. The speed is governed by the size of the pulleys driving each jig and is not adjustable.

The most important and entirely new features in the construction consist in obtaining the required movement by a rapidly rotating eccentrically balanced weight, so constructed that it can be adjusted with ease and rapidity. The revolving weight is only supported on two journals. There are no cranks, eccentric straps, or other moving parts held rigidly to a bed or other fixtures by bearings and supports. The spring connecting rods allow of free uncontrolled lateral vibra-

tion, and only transmit the required vertical vibration. There are thus only two bearings subject to wear. The whole of the power is usefully applied, none is lost in rigidly-held parts transmitting thrust and vibration to bedplates, supporting frames or other surroundings.

The whole apparatus is hung on springs, and has to vibrate. It may be objected that it will require considerable power to set in motion the whole weight of the hutch, the water and the heavy charge it contains. This is not the case. The hutch, which is not heavy, vibrates independently. That is to say, that at the down stroke it is relieved of the weight of water and ore, etc. The flexible sides of the hopper bulge inwards as it comes down, the grating being forced down into the water, and the bed remains suspended. On the up-stroke the water returns through the grating and the flexible sides bulge outwards and the bed comes down into the grating. There can be no doubt that should the vibrator be fixed to a solid "dead" mass of the same weight, the power required would be incomparably greater.

Other modifications of the principle have been constructed and proposed, as, for instance, a flexible joint, V, connecting the upper and lower parts of the hutch, as shown in Fig. 2, instead of the flexible sides. This works well and is especially useful for coarser material where the stroke should be larger and slower. Another modification is to have the vibrator attached simply to a frame in which is fixed the screen. The frame is hung on springs, and is partially submerged in the hutch of water, as in the old hand jigs, the waste being carried off over a flexible overflow attached both to the hutch and the frame. (See Fig. 3.) This gave excellent results, but is not such a neat and compact apparatus.



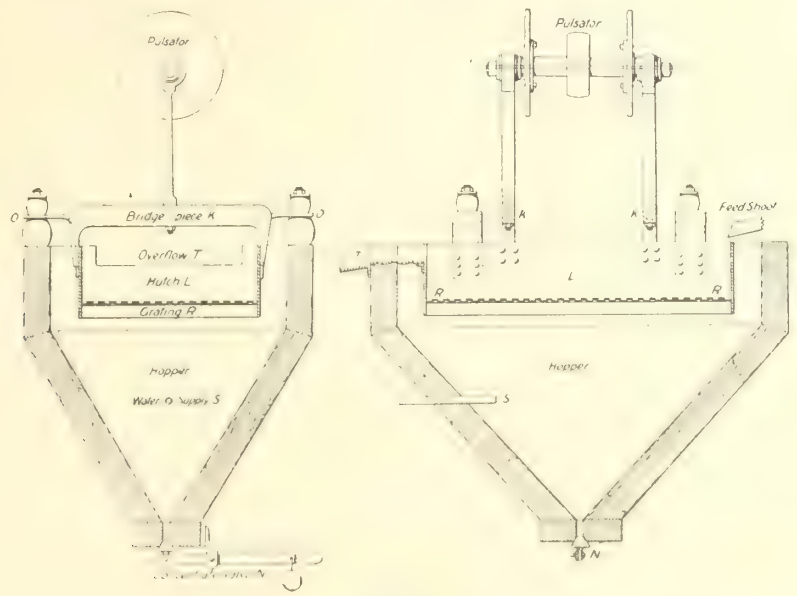


FIG. 2.

NOTE.—The flexible sides MM and flexible joint V are alternative, and are not employed together.

Another proposed modification is the application of the vibrator to a plunger in a jig of similar construction to those in general use. This modification is shown in Fig. 4, and would be designed to work with a much heavier vibrator at a slower rate of speed.

Before going into further details as to the working of these jigs it will be well to describe the nature of

the stuff they have been treating and the generol conditions under which the concentration of ore is carried on at the Calamon Mine, near Cordoba, Spain, where the trials were made.

The ore as it comes from the mine is composed of galena and blende in the proportion of about 1 of the former to 4 of the latter, mixed with carbonate of lime, slate and clay, as well as small quantities of carbonate of lead, iron pyrites, quartz, etc. The carbonate of lead is troublesome, as much of it goes with the blende, also sometimes the slate is impregnated with the carbonates and tends to give an undue lead assay in the waste. The small quantity of iron pyrites goes mostly with the galena, but it is a negligible quantity.

The quartz is generally hard and flinty, impregnated with blende, and often closely resembles good blende, though only containing 5 to 20% zinc. This tends to lower the value of the blende and raise the zinc contents of the waste. The lodes being very soft, there is an exceptionally large proportion of fine ore and slimes. As the galena and blende are somewhat intimately mixed, fine crushing is necessary. The galena is

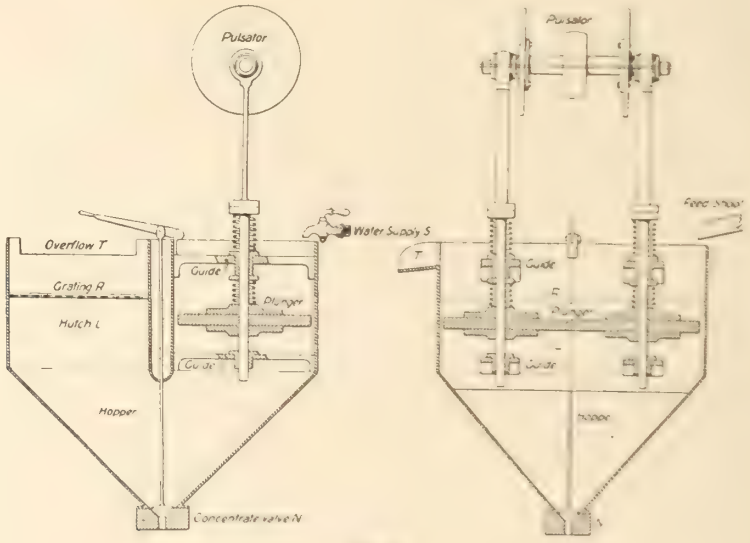

Fig. 1

concentration up to an average of 70% of lead and 7‰ of silver; the blende is 40% zinc and 1.5‰ of silver. It will be understood that with such valuable products most careful manipulation and every effort to prevent loss are necessary.

The writer was entrusted with the designing and erection of a concentrating plant to deal with these ores. The plant consisted of the usual grizzley, stone-breaker, crusher rolls, classifying trommels, machine jigs, spitzkasten and round buddles. The ore passes automatically by gravity through the whole series. A secondary complete plant deals with the secondary products. To obtain as clean a separation of the galena and blende as possible, a very careful classification was adopted and the stuff divided into eight sizes for jigging in eight four-compartment jigs of the ordinary plunger type, the first jigs treating stuff under 12 mm. and the last taking stuff passed through a 14-mesh gauze and through a spitzkasten. Thus the last jig of the old type treats stuff below 1mm., a large proportion, the galena especially, being very fine for that class of jig. Originally the stuff from over this first spitzkasten passed into another feeding the first buddle and flowing on over three ordinary conical slime separators, of increasing dimensions, each feeding a round buddle, and finally to clarifying pits.

All the jigs give clean galena in the 1st compartment, mixed galena and blende in the 2nd, clean blende in the 3rd, and mixed ore and waste ore chatts in the 4th. The waste contains about ½% of lead and 2% of zinc. The clean ore goes straight to the stores. The mixed galena and blende are first treated by hand in a jig, and give a good proportion of clean ore of each class, the true mixed ore is crushed and re-treated in the secondary plant. The chatts from the 4th compartment are all put through the secondary plant. The stuff from the buddles had all to be re-treated, even the "tails" required to be passed a second time. The "middles" and "heads" had to be treated over many times and finally washed by hand in strips or sluices to get even a fair separation of the galena and blende.

The average amount of stuff passed through the floors per day of 9 hours is 80 to 90 tons. The amount of water required is 4 or 5 cub. m. per minute, the greater part of which water is returned by centrifugal pumps after clarifying. The whole of the plant is driven by a 100 hp. high and low-pressure condensing engine.

The want of a better system of treating the slimes provided an excellent opportunity to the writer to apply the use of his new jig. Experiments were first made with a single jig. The results were so satisfactory that it was at once decided to put up a complete installation of 4 sets of 4 jigs; each set corresponding to one large jig of 4 compartments of the ordinary type. They were placed to take the stuff passing over the spitzkasten supplying the last large jig., i.e., the stuff which was before sent on to the buddles, being all the sand and slimes below 14 mesh, deprived of the greater part of their coarser ore and the coarsest sand.

By the time the stuff arrives at this point there is a large quantity of water to deal with, as at each successive operation some water is added from the grizzley down to the spitzkasten of the last large jig. The spitzkasten have, therefore, to be of large dimensions.

A separate spitzkasten supplies each set of 4 little jigs with a different size stuff; the 1st coarse silt, the 2nd fine silt, the 3rd finest silt, and the 4th almost mud.

Naturally, on account of the action of the spitzkasten, the galena contained in the different sizes of stuff is far finer than the waste. Even in the 1st jig nearly the whole of the galena will pass through a 40-mesh sieve and a large proportion through a 100 mesh. That from the last jig will nearly all pass through a 100-mesh sieve, and 50% of it through a 250 mesh.

The galena obtained runs from 75% to 65% of lead with 5 to 10% of zinc, and the blende from 45 to 30% zinc and from 5 to 10% lead. The proportion of lead and zinc in the mixed ores from the 2nd jigs varies much. The ores are separated as far as possible by hand washing. The product from the 4th jigs is turned back to pass through the same jigs again or to the secondary plant.

The waste contains about 2½% of lead and 3 and 4% of zinc. Nearly the whole of the lead contained is in an impalpable powder, for if sifted on a 250-mesh sieve, that which passes through will assay as much as 12% and what remains in the sieve only ½%.

The amount of stuff treated in these 4 sets of small jigs is from 750 to 1,000 k. per hour. They complete a consecutive series treating 12 different sizes in which the first 8 are 4-compartment jigs of the ordinary type and 4 sets of the little jigs (each set of 4 corresponding to one 4-compartment jig), beginning with 12 mm. down to below 250 mesh. The whole of the 80 to 90 tons per day is treated in the series. The average assay of the waste is less than 1% of lead, most of which is practically irrecoverable.

It may be added that the mud that will not settle in a conical slime separator 2 m. square is collected in large clarifiers and settling pits, and assays 8% of lead, 5% of zinc and 1.5‰ k. of silver. This is dried, burnt and sold to the smelters.

The cost of running the little jigs is small, two men and two boys being sufficient to run the series of 16. The power required is estimated roughly to be about 1-3 hp. per jig, or, say, 5 hp. for 16. About ½ cub. m. of water is required per minute over and above that coming down with the stuff. The cost of lubrication and repairs is also light, as there are few parts to wear, and those cheaply renewed.

Recently another complete series of 16 jigs has been erected in such a manner that they can either form part of the secondary set of jigs for treating the by-products or else be used apart for re-treating fine products from other sources, or for experimental purposes. The arrangement is the same as in the first set. They dress stuff below 14 mesh at the rate of 1 ton dry per hour. With coarse stuff the quantity would be greater. For some time they were profitably employed re-treating old dumps from the tails of buddles. In this case 50% of the galena recovered will pass through a 100 mesh. The waste carries 2½% lead, but 50% of that would pass through a 250 mesh, and 75% through a 100 mesh.

There is no doubt that these jigs will work admirably with sizes up to 8 or 10 mesh or even higher, especially as in these grades classification can be made according to size by sifting.

The jigs occupy but little space, in fact, little more than the useful surface of the grating. Complete they weigh from 40 to 50 k. each, and are thus easy to transport, and pay but little import duty in foreign customs. They can be managed by any intelligent operator, although, like all other concentrating plant, they require care and attention, especially at first. They should be applicable to all classes of ore in which the differences of specific gravity will allow separation by weight. Sizing is not all-important, although advantageous, especially in the separation of ores of little difference in specific gravity. If a classification by size could be satisfactorily made in the material for the finer sizes, in the place of the spitzkasten, there is no doubt that the separation would be nearly perfect.

The writer is confident that with some little modification the aparatus described should be applicable to the washing of very small coal. Experiments will shortly be carried out with that end in view.

EXCHANGES.

Mines and Minerals, November, 1908.—Dr. A. M. Comery, director of the Du Pont Laboratory at Chester, Pa., writes most interestingly of safety blasting explosives in Mines and Minerals for November. The term "safety explosive" is relative. A charge of 1-6 ounce of black powder may bring about a gas explosion, while under similar conditions a charge of 2 pounds of carbonite can be used with impunity.

The compulsory use of safety powders in all Belgian coal mines has reduced the number of deaths by gas or dust explosions per 100,000 miners employed from 24.5 to zero.

There are three classes of safety powders:—

1. Those containing large quantities of volatile salts.
2. Nitrate of ammonia explosives.
3. Nitro-glycerine powders.

Carbonite is the principal example of the last class. It is a slower explosive than dynamite, gives less flame, and generates less heat. It is not affected by moisture, and will detonate with a small cap.

The tests to which explosives are subjected are highly interesting. One test for strength is performed in the ballistic mortar, a device by which the recoil of a suspended steel mortar is measured on a circular scale. To determine the safety of a powder the temperature and heat of detonation are measured, the length and height of flame, the duration of flame, and the velocity of detonation.

Mining and Scientific Press, October 31st, 1908.—The Robinson mine, near Johannesburg, Sopth Africa, is the most productive gold mine in the world. Mr. J. B. Pritchard presents some facts about it in the current number of the Mining and Scientific Press. The Robinson, from a total production of 2,711,345 ounces of gold, has paid $30,000,000 in dividends. Crushing was commenced in January, 1888. In that year 7,486 tons of ore yielded 22,345 ounces of gold, an average of 59.70 dwt. per ton. Ten stamps were then dropping. The history of development is epitomized in the contrasting returns for 1907. In that year 410,927 tons of ore yielded 303,801 ounces of gold, an average per ton of ore of 14.79 dwt. Two hundred and ten stamps are now in commission. The rate of dividend payments has increased from 5 per cent. in 1888 to 24 per cent. in 1907.

The Colliery Guardian, October 23rd, 1908.—Mr. James Ashworth, in a letter to the Guardian, discusses the influence of damp air on coal dust. After pointing out the impracticability of dampening dust in a coal mine by saturating the air with moisture, Mr. Ashworth states that he "would like to have the term 'dry

air' defined authoritatively, because if air is absolutely dry no explosion is possible, but as it cannot be rendered absolutely dry, the best mode of procedure is to do as is already done in the deep mines of this country, viz., to reduce spraying to a sanitary point and thus preserve the health of our underground labor without attempting the impossible task of limiting a possible explosion by any application of water."

The South African Mining Journal, Oct. 3, 1908.— In answering enquiries concerning the most suitable form of crushing equipment for small tributing propositions, the South African Mining Journal states that small mine workers in Rhodesia favor Tremain steam stamp mills and Chilian mills. The Tremain mill weighs but 4,100 pounds. Its capacity ranges from eight to twenty tons of ore per day. It requires no engine since it is direct connected. It is self-contained and requires no frame. It can be erected speedily and as speedily dismantled. It is claimed to be an ideal mill for the prospector. In charterland, Chilian mills are greatly in favor on large and small properties.

The Mexican Mining Journal, November, 1908.— According to the Mexican Mining Journal, the deletion of Article 144 of the new Mexican mining law was due largely to "the vigorous and remarkable campaign against the law which has been waged since May by the mining interests of the country, and by those who saw the necessity of encouraging the continued investment of foreign capital for the development of Mexico's great and unrealized resources. . . . The future will demonstrate the wisdom, expediency, and necessity of the action which the Government has taken in this matter."

PERSONAL AND GENERAL.

Mr. A. J. McMillan, managing director of the Le Roi, has left for England.

Mr. W. Carlyle is expected to pay a visit to Le Roi Mine, Rossland, B.C., early in the new year.

Dr. Milton L. Hersey is visiting Toronto on business connected with the testing of railroad supplies.

Dr. Barrett, medical officer for the Guggenheims in the Yukon, is visiting Kingston, his former home.

Dr. R. W. Brock, acting director of the Canadian Geological Survey, returned to Ottawa on Oct. 28 from a three-months' visit to British Columbia.

Mr. H. W. Hardinge, of New York, has returned from Cobalt where he superintended the installation of a specially devised concentrator on the Cobalt Central property.

Mr. Robt. Mond, son of Dr. Ludwig Mond, and a prominent British metallurgist, was in Toronto recently on his return trip to England, after a three-weeks' visit to the Sudbury nickel district in connection with important experiments now in progress in the electrical treatment of nickel-copper ore.

INDUSTRIAL PAGE.

THE SULLIVAN CORLISS STRAIGHT LINE AIR COMPRESSOR.

This machine consists of a tandem compound steam engine, equipped with full Corliss valve gear on both high and low pressure cylinders, connected to and operating the two stage air cylinders, which are mounted on a frame, together with the fly-wheels, forming a "straight line" machine. This air compressor embodies the most desirable features of both the Corliss cross compound and the straight line types of construction.

The reason for adopting Corliss valve gear for this machine is that it is much more economical in steam consumption than the slide valve, with the Meyer hand adjustable cut-off. In air compressor practice the demand for air and the steam pressure vary constantly. The Corliss engine is equipped with an automatic dashpot cut-off, under the control of the engine governor, which regulates the admission of steam to the cylinders, and, therefore, the steam consumption, exactly to the load, viz., the demand for air, and the steam pressure.

Slide valve engines are fitted with a cut-off regulated by hand, which may be set at any desired point, but cannot adapt itself to changing conditions. Under the circumstances of a test, the steam pressure and air requirements are constant, so that the cut-off may be set at a point which will give favorable steam economy. But in ordinary, every-day service these factors are constantly varying. They may be low or high together, or their extremes may oppose each other, and it is on this account that the Corliss valve gear, with its automatic regulation, secures so much high efficiency.

As an indication of the steam economy of the Corliss compressor it may be said that when operating condensing, a horsepower may be generated on 14 to 16 pounds of feed water per hour, and on 20 to 22 pounds when running non-condensing. This means that the Corliss machine will use one-third to two-thirds less coal in the course of a year than the compressor with hand regulation, resulting in a saving, in that time, often sufficient to more than pay the difference in cost between the slide valve and the Corliss machine. When new plants are being installed the boiler capacity to be figured on for the Corliss type will be much less than that needed for a slide valve machine, and this item must also be taken into account. To put it in other words, the Temiskaming compressor will need a 185 hp. boiler, while a simple slide valve compressor with two-stage air cylinders, of equal capacity, requires a 295 hp. boiler.

The expense of a Corliss cross-compound plant frequently causes intending purchasers to install the less costly slide valve compressors, even when the high price of fuel renders strict economy of steam desirable. The Sullivan Class "WC" Compressor overcomes this objection, by reason of the well known structural economy of the straight line type, as compared with the duplex pattern.

The former type avoids duplication of heavy parts, such as frames, crossheads, and bearings, and lighter construction is permissible because the strains are direct

and continuous, instead of indirect and intermittent, as in duplex machines. Friction is diminished, because of the smaller number of working parts. Straight line compressors are simple and compact, and require less than one-half the house-room and foundations needed by duplex machines.

The compressor purchased by the City of Cobalt Company has a capacity of 909 cubic feet of free air per minute at 125 R.P.M. The Temiskaming machine will deliver 1,843 feet of air per minute at 100 R.P.M. Both machines compress to 90 lbs. per square inch.

The Sullivan Class "WC" Compressors, as has been stated above, consist of tandem compound steam cylinders, connected by massive cone-shaped distance pieces, in rear of which are attached the high pressure and low pressure air cylinders, crosshead and fly-wheels, mounted on a substantial iron frame. The piston rods for all four cylinders are attached, end to end, in a straight line by couplings, which permit the clearance in the cylinders to be adjusted.

The steam valve gear on both high and low pressure cylinders is of the Corliss type, with dash-pot cut-off under control of a speed and pressure governor. When the speed of the compressor reaches a point at which the air supply exceeds the demand, the speed element of this governor slows the machine down. Also, when the air pressure exceeds the point at which the pressure element is set to act, this element operates to reduce the speed of the compressor at its most economical point.

Steam passes from the high pressure to the low pressure cylinder through a pipe conduit of large diameter, heavily covered with con-conducting material.

The steam and air ends of the compressor are connected by means of a heavy foot plate and tie rods.

The inlet valves on both air cylinders are rolling valves, driven from an eccentric on the fly-wheel, through steel motion rods. The discharge valves are of the automatic poppet type, located in the cylinder heads, and so arranged that they can be removed, together with their seats, or cages, by hand, for inspection or regrinding. The design of the air cylinders, ports, and valves, is such as to reduce the elements of clearance, heating, and leakage to the smallest possible amounts, thus securing high volumetric efficiency.

The water jackets on the compressor cylinders are of unusual area, and the intercooler, through which the air passes from the low pressure to the high pressure cylinder, is so arranged that the air passes back and forth a number of times across the cold water tubes, thereby reducing its temperature to an unusually low point.

All working parts of these compressors are readily accessible while the machine is in operation. There are no parts inside the fly-wheels which require the attention of the engineer when the machine is running.

The system of oilers and lubricators on these compressors is very complete and convenient. Sight feed lubricators are employed for the cylinders and principal bearings, and other parts are oiled from a central cluster of oilers at a point convenient for the engineer.

The compressors of this class are built very substantially. All bearing surfaces are of large dimensions, and the frame, fly-wheels, crosshead, etc., are of unusual weight and solidity. These compressors will run continuously for long periods, and require only usual attention and care.

Compressors (Air and Gasoline). Canadian Rand Company, Limited...This excellently done catalogue is designed as an aid to purchasers and operators. In addition to the usual trade list of specifications, etc., there are pages of information that will prove invaluable to workers. On pages 10 and 11 are outlined the requirements, initial costs, and operating costs of compressed air installations of various sizes. There follows two pages on "Altitude Compression," in which a table of relative volumetric efficiencies is included. Following this the integral parts of the air compressor are dealt with in order. The description of the large range of types is thorough and clear. The catalogue is a credit to all concerned.

Catalogue No. 5 of the American Spiral Pipe Works, Chicago, Ill., has been received. This company manufactures, among other specialties, Taylor's spiral riveted pipe and forged steel flanges. In manufacturing this pipe, a strip of sheet steel is wound into helical shape with one edge overlapping the other for riveting the seam. The sheet is drawn and formed in such manner that a metal to metal contact in the spiral seam is obtained stretching the steel on the outer lap slightly offset, in order that pipe may be more nearly smooth inside. The riveting is done cold under enormous pressure, and not by percussion, thus insuring complete filling of the rivet holes with slight countersink. The pipe comes from the machines in a continuous piece, and is cut to any desired length.

Electrical Mining is a monthly pamphlet published by the Electrical Mining Publishing Company, Chicago. It is devoted to the interests of electric mine equipment, more especially that manufactured by the Goodman Manufacturing Company, Chicago, Ill. Each number describes the equipment and working features of some one large coal mine. The information given is timely and instructive.

Catalogue No. 127 of the Buffalo Forge Company, Buffalo, N.Y., is an exceedingly creditable publication. It deals fully with the heating, ventilating, humidifying, and drying devices of the above company.

Heretofore infusorial earth has been largely used for abrasive purposes, in the form of polishing powders, scouring soaps, etc., but of late its uses have been considerably extended. Its porous nature has adapted it to use in the manufacture of dynamite, as a holder of nitroglycerin. This same structure renders it a non-conductor of heat, and this property in connection with its light weight, has extended its use as a packing material in safes, steam pipes, and boilers, and as a fireproof material in general. In southern California the material is quarried for building stone, for which purpose it seems to be well adapted in that region of earth tremors. The Missouri tripoli finds its most important use in the manufacture of filter stones, but it is also ground and utilized as an abrasive. The Illinois product, called "silica" by the Illinois Geological Survey, but considered as tripoli for the reason that its origin is regarded as essentially the same as that usually assigned to the Missouri tripoli, is employed in the paint industry, as a wood filler, for enameling purposes, etc.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

St. Lawrence Shipments.

Glace Bay, Nov. 5.—Delays to shipping were numerous and persistent throughout the whole of October. A combination of forest fires and fogs brought about a condition of affairs that has probably never occurred before. The outputs of the Dominion Coal Co. were much curtailed in consequence, and amounted only to 265,000 tons, which is 80,000 tons less than were raised in October, 1907.

Sympathy or Superstition.

A regrettable fatal accident occurred recently at Sydney No. 1 Colliery, in connection with which the following resolution was passed by Drummond P.W.A. Lodge: Whereas the body of our late brother was taken out of the mine by means of the endless haulage, as if a dead miner deserved no more reverence than a dead horse. All this with an eye to cause the least possible loss of coal to the company, at the expense of degrading our dead brother and humiliating his fellow-workmen; whereas, The Nova Scotia Steel & Coal Company broke its agreement with the men in trying to hide from the miners of No. 1 Colliery on Thursday last the fact that one of their fellows had met a sudden and fearful death, and thus sordidly tried to increase its gains at the expense of beating down the natural sympathy that our common humanity feels and would give expression to, by suspending the chase after material gains in the presence of such a calamity to a fellow human being. Therefore, be it resolved: That Drummond Lodge will in future, should such an accident occur, and the management act as it has done in this case, throw the mine entirely idle till after the funeral of the deceased.

Be it further resolved that a copy of this resolution be placed in the minutes and another sent to the management of the Nova Scotia Steel & Coal Co.; also copies be sent to the press.

Is there any real justification for the common practice of laying a mine idle whenever a fatal accident occurs? We think not. It does not help the poor fellow who has gone to his last account. It does not help the widow, nor does it provide for the children. Would it not be more to the point if work were continued and that portion of the wages which otherwise remain unearned were given to those who, through the accident, might be brought to poverty? Such a procedure would be practical sympathy, the kind of sympathy that working men should extend to their fellows. Conditions are better in this respect than they used to be. At one time after the occurrence of a fatal accident the mine would not resume work until the funeral had taken place, causing two and three days successive idleness. It is but natural that colliery officials should endeavor to hide the news of a fatal accident, because they know that it will be the signal for all hands to leave work. This attitude of the colliery officials is forced upon them by the custom referred to. We do not think, however, that any of the Cape Breton mine officials would be guilty of irreverence to the dead, for the great majority of them are men who have wielded the pick themselves, and their sympathies are not extinguished because they bear official titles. The news of a fatal accident is at first known only to the workers in a small section of the mine and the majority of the men underground would finish their shift without this knowledge did not some person circulate the news around the mine. It is but natural that the immediate witnesses of an accident or the men in the section affected should wish to leave their work, but no argument can be adduced why everyone in the mine should go out, or should be told of the fact. We think that much more practical and effective ways of expressing sympathy can be found. The present custom is not an expression of sympathy. It is rather the slavish and unthinking following of a custom that has become a superstition.

Keir Hardie vs. John Burns.—Reference was made in these columns to the recent visit of Mr. Kier Hardie to Glace Bay. This same gentleman has been telling the British House of Commons that he was going to take the stump among the Suffragettes to wake the country from its lethargy. From recent events one would hardly imagine that the ladies in question needed any help from Mr. Hardie. In view of Mr. Hardie's solicitude for the workless and the starving in England—and they are a mighty army—we wonder why he should stay at the "Sydney" when down here. Would not a cheaper hotel have served the purpose of a gentleman who refuses to press his pants because he poses as a "workingman"? Mr. Burns gave this globe-trotting firebrand a rather cold crack recently when he informed Mr. Hardie that he (Mr. Burns) had been arranging relief works in Mr. Hardie's own constituency while that same gentleman was making the grand tour. We hope Mr. Hardie will take the hint and stay at home. He may be needed there, but he certainly is not needed here.

"Breathers" or "Pneumataphors."—Now that oxygen breathing apparatus are coming into a well-deserved prominence the need is being felt of some suitable and comprehensive name that can be applied to all types of mine rescue apparatus. At present one hardly knows what to call them "for short." Several prominent gentlemen in England seem to favor the word "pneumataphor." Prof. Redmayne uses this word in his Report on the Hamstead Fire. Mr. Blake Walker, of the Tankersley Station, used the word in a paper read recently before the Institution of Mining Engineers in Edinborough. Other names are legion. We have, for instance, "oxygen breathing apparatus." This represents one distinct type of apparatus. Then there is the "Pneumatogen" and the liquid air apparatus "Aerolith." Proprietary names will tend to become fixed in certain districts according to the type of apparatus introduced in the first instance. For example, here in Glace Bay the word "Draeger" is being used to describe all and sundry, although it is but one particular make of one type of breathing apparatus. The general name "breather" has been suggested, and although it may not be the best word, yet it is properly derived English, and describes generally the main object of all of these breathing devices. The word "respirator" has been appropriated for another purpose and is not available for our present needs. A word is required which the layman can understand and at which the learned grammarian will not recoil, nor the unlettered miner laugh. We therefore suggest the word "breather" as a generic term to include all types of self-contained breathing apparatus for supporting life in irrespirable atmospheres.

ONTARIO.

Montreal River—Silver Lake Mining Company, Limited.—Mining operations have recently been commenced by the above named company on properties situated at Silver Lake, which lies about six miles west of Elk Lake City, in the Montreal River Mining Division. The manager, A. G. McNaughton (brother of G. F. McNaughton, superintendent of the Trethewey Mine) arrived about two weeks ago from Nova Scotia with a gang of men, by whose efforts a complete camp outfit and supplies were rushed through from Latchford to Silver Lake notwithstanding the congested condition of traffic on Montreal River route. Camps are now being built and preparations being made for an active winter's work.

The directors of the company are Alex. M. Hay (president of the Trethewey Mining Company), President; Robert E. Harris, K.C. (President of the Nova Scotia Steel & Coal Co.), Vice-President; J. Strachan Johnston, Solicitor, Toronto; Thomas Cantley (general manager of the Nova Scotia Steel & Coal Co.), New Glasgow, N.S., and Gilbert Stairs, of Halifax, N.S.

The company has purchased outright mining location T. R. 597, and has acquired under Working Bond mining locations T. R. 598, T. R. 35 and T. C. 54. The first three claims are known as the Gorman and Micmac claims, T. R. 35, discovered by the Indian Micmac, being the first discovery in the Silver Lake district T. C. 54 covers mining rights under Silver Lake, and lies between T. R. 597 and T. R. 598, which are situated at each end of the lake. T. R. 35 adjoins T. R. 597 to the south and the group of properties, which embrace about 150 acres, cover a range of about a mile and a half in length on what appears to be a very promising silver belt.

BRITISH COLUMBIA.

Rossland.

The fortnight that has just passed was one of heavy shipments for this district. The big copper furnace at the Trail Smelter was put into operation recently which necessitated the Consolidated Company making heavier shipments from the Centre Star Group at Rossland, while they are also shipping from the Snowshoe and Phoenix Amalgamated Group at Phoenix. The ore shipments from the Centre Star mines for the week ending Oct. 17th amounted to 5,070 tons, making 144,767 tons sent from this mine so far this year. The Le Roi is shipping about 1,500 tons of ore per week that will return the company approximately $12.50 per ton gross and which will leave them a neat profit after treatment charges have been deducted. It is understood that Mr. W. A. Carlyle will visit the Le Roi again in the impending future in connection with the plan of operation that he has laid out for the development of the mine.

The Le Roi 2, Limited, is shipping 500 tons per week of rich ore and are carrying on extensive development at different parts of their property.

Mr. A. B. W. Hodges, local manager of the Granby, and W. Y. Williams, consulting engineer, were in the camp one day last week inspecting the work now being carried on at the Giant-California. At the present moment considerable diamond drill exploration is being done.

While considerable development work was done on many of the smaller properties here during the past two weeks, some good ore being taken out in the course of the work, still none of the lessees shipped any ore to the smelter. There are several lots of ore about ready for shipment that will be sent away during the next few days.

The Le Roi 2, Limited, has just declared another dividend of two shillings per share. This last division of profits on the operation of the Josie and adjoining mines of the Le Roi 2, Limited, makes a total of six shillings per share paid by this company in dividends so far this year. The Le Roi 2, Limited, has not only paid dividends which amount to 18 per cent. on the present value of the stock this year, but they have been doing it for years past even though they operate on a smaller scale than other copper producers in the camp. The management is to be commended for this most satisfactory result.

Phoenix.

P. F. Roosa, provisional liquidator for the Dominion Copper Co., is seeking power from the court to borrow $20,000 on behalf of his company with which to pay the men to whom wages are still owing and settle other obligations. It is stated that the solvency of the concern is beyond question, the assets far exceeding the liabilities, but the company is badly in need of some ready money to settle accounts that are now due. It is figured that the mines of the Dominion Company are worth about $2,000,000. The National Trust Co. of Toronto is trustee for the bondholders. The new company is now being organized in the East, and is expected to take over the property of the old company in a couple of weeks, when operations will be resumed.

A property that has come to the front recently in Greenwood camp, in consequence of the increased activity, is the Johannesburg, where development work has been going on all summer. The ore body is easily traced 1,500 feet across the claim and averages 60 ft. in width. The ore assays 1½ per cent. copper, $8 in nickel and a small quantity of gold and silver. The ore could be placed in the bins of the B. C. Copper Co. smelter with a tramway half a mile long, which will no doubt be the method by which it will be handled as soon as shipments are begun. On the Colorado Group, Copper Mountain, an ore body has been opened up after much perseverance, and in the face of many discouragements that assays $9.10 gold and 18.97 per cent. copper.

J. Langeloth, of New York, president of the Granby Con. Mining, Smelting & Power Co., with J. C. Graves, of Spokane, general manager, and A. B. W. Hodges, local manager, inspected the Phoenix mines last week. The president was pleased with the way things looked around the mines. The smelter was also visited by the party and the important work now in progress there gone over.

The augmentation of one of the smelter furnaces has now been completed. This furnace is four feet longer and wider than the other seven, which will be enlarged in turn one at a time. The capacity of this furnace has been increased about 25 per cent. The building for the two big convertors on order is about ready for them. These convertors are large enough to handle the matte from all eight furnaces after being enlarged, when they are running full capacity. The ore shipments from the Granby are running from 21,000 to 22,000 tons per week. As the mines are closed down on Sunday lately this affects the shipments to some extent.

The Consolidated Company is producing about 2,500 tons per week from the Snowshoe, and small shipments are also being made from the War Eagle group, which, as the company already has a War Eagle group at Rossland, are known as the Phoenix Amalgamated group, for purpose of distinction. Development work is being pushed on both of the Phoenix groups, and in the course of work on the Phoenix Amalgamated they have opened up a 70 ft. ledge of copper ore of similar grade to that found in the Granby, which adjoins this property.

About thirty men are employed at the Oro Denoro, and approximately 700 tons of ore per week have been sent out during the past fortnight.

Work has been discontinued on the Little Bertha, North Fork. Considerable stock changed hands on the basis of work being resumed on this property, and there will be a few disappointed buyers if development is not continued and some tangible results obtained.

A 200-ft. tunnel is to be driven on the ledge at the Bell mine, Wallace Mountain.

The operators of the Sally mine, who have shipped 108 tons of valuable ore already this year, have a carload of rich ore about ready for shipment. Nine men are working at the mine.

The tunnel is in on the Woodburn 280 feet now, and some likely looking stringers and other indications are being exposed.

Work has been resumed on the Kingston at Hedley. This group consists of the Kingston, Metropolitan, War Horse and Grand View claims, which are nearer to Hedley than the rich

Nickle Plate properties. A strong 30-ft. vein exists on the Kingston, where most of the development has been done. This ledge carries chalcopyrite and pyrrhotite, and on the foot wall there is 8 to 10 ft. arsenical iron ore carrying gold. Assays range from $17 to $40. Most of the stock of this company is owned in Quebec. The property is regarded favorably, but much development work yet remains to be done. A force of eight men is now at work.

Nelson.

The leading feature of the mining situation here during the past week has been the heavy shipments of zinc made by the Whitewater mine. This company shipped 180 tons of zinc during the week, making a total of 6,375 tons for the year to date. Nearly all of this has been sent to Antwerp. The Whitewater properties now rank second in the shipping list for this section, the St. Eugene heading the table, and shipping over 900 tons of silver lead ore per week. The Silver Hustler, Rio, Maestro, and Black Diamond have lately joined the list of shippers, having sent out their initial shipments this year. Several more mills have started up as well.

The operators of the Aurora mine at Moyie have bought the boiler and compressor formerly used at the Dominion Copper Company's Brooklyn mine, Phoenix. There is a two foot ledge of clean shipping ore in the mine. As soon as the machinery is installed this ore will be taken out and shipments will be made across Moyie Lake as soon as the ice forms upon it.

Vancouver.

J. Cronin, formerly with the St. Eugene Co., has returned after a season's work on the property he has bonded in the Babine district. About 280 feet of development work in tunnels and shafts was done on the rich surface showing, the deepest shaft being 53 feet, but very little was determined as to how the ore will look at depth. In fact, the results were rather disappointing in some places. Another season's work will show the value of the group.

A find of ore assaying 287 oz. silver, 50 per cent. lead and $5 in copper has been made by H. Harris, of Rossland. The find is eight miles from Hazelton in the hills. It is the intention of the owners to ship from the property next year. There is a considerable quantity of ore in sight.

The Ingenica Mining Co. have taken an 8-ton plant into their mines over a rough road.

A large body of iron ore, similar to Swedish iron has been located on Douglas Channel.

Heavy snowstorms have driven the prospectors out of the Northern hills for this season. Most of the men have left their claims and have come out to the coast cities. Those who have taken up land have prepared for the winter and will remain in the valleys on their locations until spring.

An extensive deposit of bornite, carrying $50 to $60 in values, has been exposed in the Cornell mine.

R. C. Campbell-Johnson, of this place, has returned from a visit to the Queen Charlotte Islands, and says that these islands will excel as copper producers the famous Coeur d'Alene district of Idaho with its lead. Of course, that remains to be seen, but there is no doubt these islands are very rich and will undoubtedly revolutionize the mining industry of this coast.

GENERAL MINING NEWS.

NOVA SCOTIA.

Amherst, Nov. 3.—James Carson, a native of Halifax, died at Chignecto mines to-day. Carson was injured in attempting to prevent a box, which had become unbalanced, from running down the shoot. Carson was 27 years of age.

Stellarton.—The Allan shafts of the Acadia Coal Company are now well equipped. The new cages, when installed, will hold four boxes, and will permit of hoisting between 2,500 and 3,000 tons of coal per day. The present output is about 370 tons per day.

Cobalt.—On October 27th a train of 13 cars, loaded with medium and low grade silver ore, left Cobalt for Denver. The following mines contributed to this special shipment:

La Rose, 4 cars.
Kerr Lake, 2 cars.
Temiskaming and Hudson Bay, 2 cars.
O'Brien, 2 cars.
Temiskaming, 1 car.
Crown Reserve, 1 car.
Chambers-Ferland, 1 car.

This shipment is to be a speed trial. It is hoped that time will be saved by the mines joining hands in this way.

The Northern Customs smelter, formerly the Muggsley concentrator, has since July 15, treated over 4,000 tons from the Silver Queen dump, 1,000 tons from the Townsite, and over 1,500 from the City of Cobalt.

Sudbury.—Mr. R. Hedley has thirty men employed at the Leckie mine, Long Lake. Work will be carried on throughout the winter.

Major R. G. Edwards Leckie has left for Pedro Lake, north of Wahnapitae, prospecting for gold. W. Errington accompanies him.

Port Arthur.—There is talk of reopening the Foley mine, near Mine Centre, Rainy River district.

ALBERTA.

Lethbridge.—The new slope of the Royal Collieries is down 200 feet. The water system is completed, work on the tipple has been completed, and a large rooming house for the accommodation of the men is being erected.

BRITISH COLUMBIA.

Nelson, Oct. 31.—The total zinc ore shipments for the year from the Whitewater mines, near Sanden, amount to over 6,000 tons. All but 300 tons have gone to Oklahoma. The remainder has been shipped to Antwerp.

Rossland.—The Canada Zinc Company started work on October 15. Construction of the plant has taken two years.

Phoenix.—Towards the last of October the Phoenix Amalgamated, heretofore known as the War Eagle (not to be confused with the War Eagle of Rossland), became a shipper. It is the property of the Consolidated Mining and Smelting Company.

Victoria.—The steamer "Princess Ena" reached here on October 30 from Ladysmith. At Ladysmith she landed 1,000 tons of ore from the Japanese mines of the Awaya-Ikeda Company at Ikeda Bay. The Ikeda Company expect to ship 1,000 tons per month.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The annual report on the mines and quarries of the United Kingdom for 1907 gives the total value of the mineral output at £135,279,008, being an increase of £29,436,096, as compared with 1906. This is attributed to the increased production and higher price of coal. The total output of coal amounting to 267,830,962 tons, valued at £120,527,378, is the highest hitherto recorded, the figures for 1906 being 251,067,628 tons, valued at £91,529,266. Other leading items are iron ore, 15,731,604 tons, valued at £4,433,418; clay and shale, 14,827,895 tons, value £1,850,387; and limestone, 12,509,142 tons, value £1,323,624.

A large new coal-washing plant, designed for an ultimate capacity of 3,000 tons per 24 hours, has been built at Cardiff by the German firm of Meguin, for the Carbonifera Industriana Italiana of Genoa, Italy. The latter company have large briquett works in Italy, for which the Cardiff plant will supply material, the present power of production being 1,500 tons daily.

GERMANY.

Owing to the increasing price of wooden railway ties the management of the Prussian Government railways has decided to make an exhaustive series of tests as to the suitability of ferro-concrete ties.

The German Government has sent invitations to all petroleum-producing countries to take part in an international congress, which will probably be held at Karlsruhe, for the purpose of unifying the methods for testing and analyzing petroleum.

The use of the electric furnace for steel manufacture is increasing, especially in localities where mineral fuel is not available. Herr Georg Fischer has erected at Schaffhausen an electric steel works for the manufacture of steel castings by the Heroult process, in which castings up to one ton in weight can be produced.

AUSTRIA.

A number of anciently-worked gold mines in Bohemia and Moravia have been acquired by a company in Pribram, and will shortly be reopened.

AUSTRALASIA.

New South Wales is apparently destined to become an important shale-producing country. A wealthy British syndicate is making large expenditures in preparing for the development of enormous shale deposits in the Wolgan Valley, west of Sydney, and another with a nominal capital of £300,000 is being organized in Australia and England to develop the extensive shale-bearing district near Murrurundi, in the northern part of the State, where a lease of 3,000 acres has been secured.

The discovery of gold at a depth of 4,504 ft. in the Victoria Quartz mine, Bendigo, Victoria, is giving an impetus to deep sinking.

RUSSIA.

The South Russian coal market has been considerably affected by the decision of several southern railways to give up the use of coal and return to petroleum fuel, which they abandoned some years ago. The export trade is consequently likely to be increased.

NORWAY.

A concession to mine 36 iron ore claims at Fughestrand and Skravlaa in Hemnos Herred, Nordland, has been granted to Sixtus Sjoberg, of Stockholm, for 75 years. Very rigid conditions are laid down, including the payment of royalties, the satisfactory working of the properties, and the employment of Norwegians only, and it it stipulated that the concessionaire must not join any combination for "bulling" ore prices.

SOUTH AFRICA.

The average working cost per ton of sixty Rand companies for August was reduced to 17s. 4d., being 5d. less than for July. In January working costs stood at 19s. 7d. per ton, the saving effected in the meantime amounting to 10 per cent. This has been largely secured by substantial reductions in the pay of native laborers.

The South African Option Syndicate, Limited, is offering rewards up to £20,000 and an interest in the claim for the discovery of a diamond pipe in the Somabula diamond area of about 65 square miles in extent.

UGANDA.

A new gold field has been found in the territory west of Lake Albert, Nyanza, where gold has been discovered in Kakoi River gravel, and in the Adz Valley. The country is easily accessible.

UNITED STATES.

A new gold district has been discovered in New Mexico and named Sylvanite, from the character of the ore, which is a gold-silver telluride. Several rich properties have been opened up.

A stratum of sulphur 325 ft. in depth has been tapped in Liberty County, East Texas, which is believed to be the richest deposit known anywhere.

The Idaho Smelting and Refining Co.'s plant at Ponderay, Idaho, which has been reconstructed in the interests of the small mine owners of Idaho and Montana, has started operations.

A controlling interest in the Bullion-Beck mine, one of the oldest silver-lead mines in Utah, which has been operated since 1876, has been secured by the United States Smelting, Refining and Mining Company.

COMPANY NOTES.

THE HASTINGS (BRITISH COLUMBIA) EXPLORATION SYNDICATE, LIMITED.

Directors' Report.

The Directors have the pleasure to present the Tenth Annual Statement of Accounts and Balance Sheet for the year ended 31st May, 1908.

It will be seen that the financial position of the Company shows considerable improvement. The Cash on hand and at Bank amounts to £2,693 13s. 4d., being an increase of £1,009 19s. 4d., as compared with the corresponding period of 1907. The Administration Expenses for the year in London and British Columbia, which include Income Tax, Fire and Accident

Insurance and Government Ore Tax, exhibit a decrease of £87 6s. 7d., and there is a reduction of £1,274 11s. 3d. in the cost of Development Work.

The Ore shipped to the Smelters during the period under review netted £10,146 1s., that is after deductions for freight and treatment; the figures for the past four years being—

For the year ended	31st May, 1905	£10,099	16	10
" "	31st May, 1906	10,070	5	8
" "	31st May, 1907	9,574	9	1
" "	31st May, 1908	10,146	1	0

The accompanying advices from Mr. Leslie Hill, Local Representative and Consulting Engineer in British Columbia, will be read with niterest by Shareholders. The practice of publishing extracts from his Annual Report has been adopted by the Directors for several years and forms a continuous and descriptive history of the Company's mining operations. Mr. Hill writes:—

"Arlington Mine and Group.

"The development work done during the year at the Arlington Mine consisted of drifts 504 feet, crosscuts 25 feet, winzes 4 feet, and raises 430 feet. On the Micawber Claim the development work done was drifts 235 feet, raises 119 feet. There was also a raise of 46 feet put up on the ground of the Canadian King. The total development work amounted to 1,188 feet, and the cost of labor was $9,314.63, or $7.84 per foot.

"1,220 mine-cars of Ore and 7,110 mine-cars of waste were taken from the mine, and the stopes were filled with waste as far as practicable.

"Hauling by wagon commenced on 11th June, 1907, and ceased on 20th November, during which time 169 wagon loads of Ore were hauled to Erie and 26 car loads of Ore were shipped to the smelter at Trail, B.C. Sleighing commenced on 24th December and lasted up to March 11th, 1908, and 126 sleigh loads of Ore were hauled to Erie and 28 car loads of Ore shipped to Trail.

"In 1908 we commenced to haul by wagon on 25th May and 3 wagon loads of Ore were hauled to Erie during the month, the returns for which will appear in the accounts for 1908-1909.

"During the year 1,241.6 tons of Ore were shipped, which realized $53,143.20 net smelter returns, and $81.04 for Government Bounty on Lead Smelted, making a tital of $53,224.24, or $42.86 per ton.

"The cost of mining, sorting and shipping, including development work, was $27.06 per ton, made up as folls:—

Development (labor)	$7.51
Stoping	8.54
Sorting and Tramming	3.87
Assaying, Surveying, Surface and General Expenses	1.67
Supplies	2.25
Hauling to Erie and Loading on Cars	2.03
Insurance	.38
Ore Tax	.71
Miscellaneous Expenses, less Boarding House credit of $34.50	.10
	$27.06

"Total cost per ton of Ore, sorted and shipped, $27.06, leaving a gross Mine profit of $15.80 per ton, being 37.05 per cent. of the net Smelter Returns. This compares favorably with the results of the previous year's operations, as the Smelter Returns were $5.90 per ton higher and the expenses $1.49 lower, but the tonnage shipped was 167.38 tons less.

"Development.—The No. 7 North Drift was extended 259 feet, the No. 8 North Drift 97 feet, and the No. 9 North Drift 33 feet. A shoot of Ore was found on the No. 7 North Level, north of the Canadian King line and on the Directorate Claim. Some Ore was stoped from this shoot and there is still Ore in the raise. A raise has been put up from the No. 7 North Drift to a point south of the Canadian King line. This raise crosses the line of the Canadian King and connects with the old No. 4 Level which has been extended northerly. There appears to be a considerable shoot of Ore exposed by the raise, partly in the Company's ground and partly in Canadian King ground.

"A second and higher Adit was driven on the Micawber Claim a distance of 250 feet, and then raised to surface. At 50 feet up the raise we encountered a vein, and are now driving on this vein. It would seem that this should be the Arlington vein, but so far we have not found any pay Ore.

"East Kootenay Claims.

"No work has been done on these claims during the year. It is reported that a small vein of pay Ore has been found on a claim adjoining one of our claims and also joining a claim of the North Star Mining Company. Also it is stated that a large lead containing low grade Lead and Zinc Ore runs from the North Star workings diagonally across to the Mine of the Sullivan Mining and Smelting Co., and that this lead crosses some of your Claims. The value of the low grade Ore on this lead depends upon the Zinc situation—that is to say, whether Zinc Ore is to be admitted free into the United States, and also as to the success of some new methods of Zinc smelting which are about to be tried on a commercial scale in British Columbia."

Blairmore Coal Lands.

It is with much satisfaction the Directors announce that the final instalment on these important properties has now been paid to the Dominion Government of Canada, and the Patents for the lands have accordingly been applied for. This asset appears in the Company's books at £7.348 15s. 4d., an amount commensurately small with the estimate placed upon the property by experts who have visited the Coal Fields. There have been several local enquiries during the past twelve months by parties desirous of opening negotiations to purchase, but your Directors have not entertained any of the proposals submitted to them.

In April last your Directors had the advantage of a visit to this country by Mr. Leslie Hill, your Manager in British Columbia, and derived much benefit from the opportunity thus afforded for an interchange of views regarding local affairs of the Company, which it is gratifying to repeat, continue to be most carefully conducted under his able supervision.

It is with sincere regret that the Directors have to record the death of Sir Edward Birkbeck, Bart, who was identified with this Company from its inception, and the loss of his services is much to be deplored.

In conformity with Clause 66 of the Articles of Association, the Directors have elected the Hon. C. Melton Astley to fill the vacancy on the Board, and at the Meeting the Shareholders will be asked to confirm his appointment.

In accordance with Clause 69 of the Articles of Association, Mr. James Head retires by rotation from the Board, and, being eligible, offers for re-lection as a Director.

By Order of the Board,

E. HOLT,

Secretary

Auditors' Report.

In accordance with Section 19 of the Companies Act, 1907, we report that we have audited the Balance Sheet of the Hastings (British Columbia) Exploration Syndicate, Limited, dated 31st May, 1908, as above set forth. We have obtained all the information and explanations we have required with reference thereto. In our opinion such Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of the Company's affairs, according to the best of our information and the explanations given to us, and as shown by the Books of the Company.

JAMES HEAD, Chairman.
G. L. WHATELY, Director.
E. HOLT, Secretary.

The Buffalo Mines, Limited, will more than double its dividend after the new year. Shareholders in the Buffalo now receive three per cent. quarterly, but this will be increased to five per cent. quarterly, making a regular annual dividend of twenty per cent. per annum. In addition a bonus of one per cent. per month will be paid, increasing the return to the shareholders to thirty-two per cent. per annum. The Buffalo has already paid almost a quarter of a million dollars on a capitalization of $1,000,000.

Directors of the Silver Queen have declared the third quarterly dividend of 2 per cent. payable December 1 to shareholders of record November 15. Comment was occasioned by the fact that this quarter the Queen is only paying three per cent., whereas in the two previous quarters it paid in addition a bonus of two per cent. a quarter. The Silver Queen management explain that the two bonuses referred to were paid for the purpose of bringing the dividend return on Queen up to 12 per cent. per annum for the past two years. Last year there was one dividend of 8 per cent., which, with the two bonuses this year, gives the holder 12 per cent. Three per cent. quarterly is being paid, and the management are not likely to increase it while silver remains so low.

The regular monthly meeting of the directors of the Granby scheduled for Nov. 4th in New York was postponed for one week.

An interim dividend of two shillings per share has been declared on Le Roi.

FOSTER COBALT MINING COMPANY.

The annual meeting of the Foster Cobalt Mining Company was held at McConkey's on the afternoon of November 4. The meeting was exceptionally free from acrimony.

The financial report submitted showed a cash balance on hand and in the bank of $17,342.18. There is a further sum of $24,185.42 due from ore sales.

The president's report, reprinted below, indicates that no high-grade silver ore is on hand for shipment. A parcel of thirtytons of ore high in cobalt is ready to send to the smelter. Ore on the dumps is valued at from $15,000 to $50,000. The dump stuff will be shipped to a custom concentrator during the winter.

Following is the report presented by the president at the meeting: In presenting the financial statement of the company for the year ending September 30, 1908, your directors do so with that natural regret which must be felt when any limited company does not report dividends paid upon its share capital. However, your board has the consciousness of having accomplished everything that was possible under the circumstances. The year's development has been extensive, though not productive of results in high silver values that reasonably had been looked for. During the year every economy has been practised and the operations have been conducted along most approved mining lines. During the past sixty days your Board has sought the advice of three eminent mining engineers who have examined the property. Their examinations having been made as a matter of courtesy and compliment to individual members of the Board, it is not possible to use their names in connection with their reports. However, they are men of such standing in their profession that your Board transmits to the shareholders the results of their examinations with the assurance that their reports may be relied upon. In brief, their conclusions are as follows:—

The main workings of the property (veins 5-1) have been carried to a depth of 225 feet. While the fissure vein continues strong, indicating possibly one of the strongest fissure veins in the district, no high values in silver have been encountered, and therefore it has been determined not to sink any lower in this shaft at this time. It is strongly recommended by all engineers hat our work of drifting out under Glen Lake be continued and prosecuted as rapidly as possible in order that the diabase contact believed to exist under the lake may be fully evplored. It would only be possible to make this drift from the 225-foot level, because of the depth of water in the lake and the fact that the top of the main shaft is at a considerable elevation above the lake.

The cross-cutting from vein No. 8 in the direction of veins 6 and 2 is also strongly endorsed, and since this cross-cutting has been undertaken one additional vein has been discovered which, while still running only in cobalt values, indicates the wisdom of this method of development. Only the actual work of drifting and cross-cutting can demonstrate the existence or non-existence of high values.

Your directors have aimed to make public every reasonable statement concerning the property, but are constantly confronted with the difficulty of making statements which might be too encouraging on the one hand or on the other hand would not do full justice to the possibilities of the property. It is just such a condition that confronts them to-day. There may be great possibilities as a result of the present outlet development. Eqaully true, this development may not be productive of any greater results than during the past months, therefore it but remains for your Board to pursue operations along lines clearly indicated by the best engineering advice available. That it will be done expeditiously and economically is the only warrant that the Board can give.

You will observe that since the last annual statement there have been no sales of treasury stock.

The present stock or ore on hand ready for shipment consists of about thirty tons of ore high in cobalt, but low in silver. The prospect for early shipment of high-grade ore is uncertain, depending entirely upon the results of the development indicated above.

The results of some concentration done on ores from the dumps confirm the belief that these dumps contain values variously estimated at from $15,000 to $50,000. During the coming winter months, when transportation is cheap, large quantities of this ore will be sent to the concentrator, where arrangements are in effect under terms distinctly favorable to the company.

Should the shareholders conclude to re-elect the present Board of Directors, a policy of rigid economy and some further reduction in cost of operation will be adopted.

The officers were re-elected as follows: John T. Kent, President; E. F. B. Johnston, Vice-President; Directors, Mayor J. Oliver, Simon Dyment, C. Jackson Booth, W. H. Fisher, and George H. Doran.

STATISTICS AND RETURNS.

The output of the collieries of the Crow's Nest Pass Coal Company for the week ending October 23rd was 19,287 tons; daily average, 3,214 tons. For the corresponding week of last year the output was 21,996, a daily average of 3,666 tons.

The output of the collieries of the Crow's Nest Pass Coal Company for the week ending October 31 was 18,835 tons, a daily average of 3,139 tons. For the corresponding week of last year the output was 21,172 tons, a daily average of 3,529 tons.

The output of the Crow's Nest Pass Company's collieries for the week ending November 6th was 19,634 tons, a daily average of 3,272 tons.

Nova Scotia Steel & Coal Company's output for October was 70,160 tons of coal, against 57,200 tons in September and 57,480

in October a year ago. The total for the year to date is 574,670 tons, against 528,720 tons in 1907. The pig iron output this October was 5,800 tons, and steel 7,750 tons. This is a record for both coal and steel.

The Dominion Coal Company's October shipments were 263,000 tons, compared with 339,573 tons in October, 1907. A large decrease was due to the boats' delay in getting up the St. Lawrence owing to the heavy fog and smoke prevailing. For ten months coal shipments were 1,257,370 tons, contrasted with 990,492 tons in 1907, an increase of 266,878 tons.

Dominion Coal's output was light for October, election day being practically a holiday at the mines. Up to date, however, the output is approximately 203,000 tons ahead of a year ago. The output in tons follows:—

	1908.	1907.
January	314,108	252,248
February	285,649	225,988
March	346,529	212,831
April	298,745	316,384
May	332,588	237,269
June	347,000	319,000
July	368,000	321,000
August	310,000	316,302
September	263,000	296,889
October	264,959	339,573
Totals	3,130,578	2,927,484

The output of the Dominion Iron & Steel Company for the month of October is as follows: Pig iron, 21,000 tons; steel ingots, 22,500 tons; shipments, 18,000 tons.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp for the week ending October 24th:—

	Ore in lbs.
*Coniagas	64,498
Cobalt Lake	62,940
Crown Reserve	126,000
Chambers-Ferland	140,000
Drummond	125,000
La Rose	335,000
McKinley-Darragh	57,000
Nipissing	189,380
O'Brien	192,140
Silver Leaf	114,870
Temiskaming & Hudson Bay	60,000
*Trethewey	132,000

*Partly concentrates.

The total shipments for the week were 1,600,128 pounds, or 800 tons. Total shipments from January 1 to date, 35,340,743 pounds, or 17,670 tons.

Cobalt ore shipments were heavy for the week ending October 31st, due no doubt to exhibition trainload sent to the Denver smelter. Thirteen mines shipped 1,706,690 pounds, or 853 tons of ore. The shipments from the camp for January 1 to date were 36,589,559 pounds, or 18,294 tons.

Shipments for the week and year were, in pounds:—

	Week.	Since Jan. 1.
Buffalo	.....	912,950
*Coniagas	.....	1,032,853
Cobalt Lake	.....	404,623
Crown Reserve	127,000	594,688
*Cobalt Central	43,000	487,075
Chambers-Ferland	60,440	383,890
City of Cobalt	42,000	1,239,300
Drummond	100,000	1,291,520
Foster	.....	297,300
Kerr Lake	184,050	1,091,394
King Edward	.....	127,240
La Rose	386,330	7,331,970
McKinley-Darragh	.....	2,54,770
Nipissing	187,260	2,941,610
Nova Scotia	55,400	447,675
Little Nipissing	.....	40,110
Nancy Helen	.....	367,427
O'Brien	190,370	5,846,157

Silver Queen	.....	1,555,990
Townsite	.....	251,700
Temiskaming	63,000	931,620
Temiskaming & Hudson Bay	185,160	2,073,666
*Trethewey	.....	2,042,476
Watts	.....	561,680

*Partly concentrates.

Cobalt ore shipments for the month of October fall below those of September and August, but lead every other month in the year. The La Rose was far away ahead of the other mines, with total shipments for the month of 1,$92,120 pounds, against 822.040 pounds for the Nipissing, 665.160 for the T. & H. B., 673,770 for the O'Brien, and lesser amounts for the others.

Some well-known mines do not appear in the list at all. Shipments from the camp by months, in tons, were:—

Month.	1907.	1908.	Inc.
January	980	1,325	345
February	903	1,174	270
March	1,027	1,832	805
April	533	1,317	784
May	1,158	1,601	443
June	1,939	1,581	*358
July	1,327	2,022	695
August	1,139	2,366	1,227
September	760	3,322	2,562
October	1,292	2,325	1,033
Total	11,058	18,864	8,806

*Decrease.

B. C. ORE SHIPMENTS.

Nelson, B.C., October 24.—The following are the detailed shipments from the various mines and the receipts of the smelters of the districts of Southeastern British Columbia for the past week and year to date:—

BOUNDARY ORE SHIPMENTS.

Mine.	Week.	Year.
Granby	21,840	842,684
Mother Lode	9,074	198,810
Oro Denoro	680	51,686
Snowshoe	2,492	16,831
Phoenix Aamalgamated	120	205
Other mines	....	22,248
Total	34,206	1,132,464

ROSSLAND.

Centre Star	4,007	139,003
Le Roi	917	63,400
Le Roi No. 2	479	24,02.

Montreal	San Francisco	Winnipeg
Nanaimo	Sault Ste. Marie	

NEW YORK, 16 Exchange Place
LONDON, England: 2 Lombard St., E.C.

Branches at COBALT and LATCHFORD, in the silver mining camp of New Ontario.

An Ideal Investment

Safety and quick returns of trade with profits of mining deals. Pre-organization offer. 150% advance on incorporation. Prospectus. Invesigate. Or if you want to buy, or sell, a mine or good prospect of any Kind, write us fully and confidentially. That's part of our business.

Canada Mines Syndicate,

Box 189. Sherbrooke, Que.

FOR SALE

Copper and Lead Mine

on Lake Superior, near Port Arthur, four hundred acres; old title; considerable development done; good mineral showings; bargain price; easy terms on working option. For further particulars, apply to

W. L. HIME,

160 Dowling Ave., Toronto

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary. and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

Some Books of interest on Mining to be had from the Book Department of the Canadian Mining Journal, Toronto, Ont.

The Copper Mines of Lake Superior. By T. A. Rickard. An attractive volume of 165 pages, handsomely illustrated. The present work consists of a group of interesting articles in a revised and amplified form, which were originally published in the columns of The Engineering and Mining Journal during the latter part of 1904. Octavo, cloth. Price, $1.00.

The Chemistry of Cyanide Solutions Resulting from the Treatment of Ores. By J. C. Clennell. Price, 2.50.

Across the San Juan Mountains. By T. A. Rickard. A graphic description of a picturesque ride of 400 miles on horseback through the San Juan Mountains in South-western Colorado. The work is written in vigorous and buoyant style, and the information contained therein, while appealing specifically to the geologist, prospector, and mining engineer, will also prove of great interest and enjoyment to the general reader. Small quarto, cloth, ornamental covers and profusely illustrated. Price, $1.00.

Ore Deposits. A discussion republished from the Engineering and Mining Journal, containing the recent contributions on the origin of ores. By S. F. Emmons, W. H. Weed, F. L. Ransome, C. R. Van Hise, T. A. Rickard, and C. W. Purington. The matter originally published has been revised and amplified. A review of the subject by the Editor of the Engineering and Mining Journal is added. It is an up-to-date discussion of a subject which is of great interest to mining men. The book contains 100 pages. Cloth. $1.00.

Mineral Resources of Canada. An illustrated handbook giving a brief outline of the economic minerals of Canada, and sketching the mineral resources of each province. The book contains 140 pages, 32 color engravings of the most important minerals. The latest mineral Resource Map of the Dominion, showing the chief mineral deposits, is also included. No such work has been attempted in Canada before. This volume should be in the hands of every one interested in the mining industry. The price of this volume is extremely moderate. $1.00.

Minerals and How They Occur. By Willet G. Miller, Provincial Geologist, a volume of 250 pages, illustrated. This book is especially adapted to the prospector for minerals, as he must have a knowledge of mineralogy before he can properly understand the character of rocks and the effects which are produced on them by atmospheric and other agencies. If you are a prospector this is the work for you. Price, $1.00.

The Sampling and Estimation of Ore in a Mine. By T. A. Rickard. Sampling and mine valuation are eminently practical subjects, and in this work they are handled in detail by engineers and experts of the first rank, who have had world-wide evperience in these matters. To students, mine directors, mining engineers, mine investors, and engineers generally, this volume will be found extremely useful. Octavo cloth, profusely illustrated. Price, $2.00.

Rocks and Rock Minerals. By L. V. Pirsson, Professor of Geology in Yale University, 414 pages, 74 figures, 36 full-page half-tone plates. Not all mining men have an intimate knowledge of petrology, or the science of rocks. Even those who have had the advantage of a college course find that only a small residue of what they learned adheres to them. Most text-books on the subjects are cast into forms that repel the lay reader. Hence it is not easy for the beginner to acquire the rudiments of the science. "Rocks and Rock Minerals" is an attempt to present the outlines of petrology in such a way as to give an intelligent idea of the subject to readers quite unacquainted with the microscopic standpoint. Rocks and rock minerals are dealt with entirely from a megascopic, or practical outdoors, point of view. The book before us attains the desired object of giving the reader a knowledge of rocks and rock minerals without recourse to the microscope. It is a very fair introduction to the study of geology generally. Part III., in which igneous, stratified, and metamorphic rocks are described, is an excellent treatise in itself. Simplicity is the keynote of the book. Cloth. Price, $2.50 net.

A History of Cobalt. During the summer of 1907 the Canadian Mining Journal published a beautiful illustrated souvenir volume. Included in this volume is a history of the early days of Cobalt. An excellent map of the district accompanies the book. Price, $1.00.

The Electric Furnace. By Alfred Stansfield, D.Sc., A.R.S.M., Professor of Metallurgy, McGill University. There has long been need of a good book on electric furnaces. The increased importance of the subject and the great value to metallurgy makes this book most timely. 211 pages (illustrated) 6 x 9 inches. Price, $2.00.

Simple Mine Accounting. By David Wallace. A neat compact description of the simple methods of keeping mine accounts. Mr. Wallace is an expert mine accountant and in this book he outlines briefly and simply the kind of accounts and records which a small mine should keep. 64 pages 6 x 9 inches, with bookkeeping forms. Price, $1.00.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

THE OFFICIAL MINING DIRECTORY OF MEXICO. 1908-1909

CALLE DEL ELISEO, 37, MEXICO, D. F.

EDITORS: JOHN R. SOUTHWORTH, F.R.C.S. and PERCY C. HOLMES.

"The Official Mining Directory of Mexico" is the 10th volume of the series of works, devoted to the propagation of knowledge concerning the resources of M exico, which has been issued from these effices under the authorization of the Mexican Government, each co py being duly impressed with the Federal Seal of the United States of Mexico.

The contents of the work comprise:

Alphabetically listed descriptions of over 1,500 M ining companies operating over 7,000 mining properties in Mexico. Only such companies as employ more than 20 men, or use power other than animal power, are listed.

The data given, in respect to these companies, is exemplified in the specimen shown on this sheet. It includes name of company, home office address, mine o ffice address, president, secretary, treasurer, directors, manager, superintendent, subordinate staff, where and when incorporated, capitalization, issued stock, par value of shares, additional financial data, names of m ines, number of claims, product, description of ore, description of geological formation, kind of power used , number of horsepower used, description of mine workings, capacity of treatment plant, cyanide plant, smelter , etc., number and weight of stamps, number of grinding mills, number of tube mills, number of concentrators, number of men employed, contemplated improvements, general remarks.

The volume is illustrated by over 200 photographs and maps, showing the leading mines, mills, smelters, and camps in the Republic.

Tables of utility to mining men, shippers and inv estors are given.

A Spanish-English glossary of Mining Terms make s the translation of letters from Mexican miners possible, where a dictionary would be valueless.

Preliminary to the actual directory, there are spec ial articles, written by competent Mexican and foreign authorities, on:

"The History of Mining in Mexico."

"Number and Geographical Distribution of Mines in Mexico."

"Foreign Investments in Mexican Mining Securiti es."

"Progress of the Metallurgy of Gold and Silver in Mexico."

"The Mexican Mining Chamber."

"The Mexican Mining Laws."

"The International Bureau of American Republics ."

The edition presented to your notice is in English, and contains 280 pages, measuring 13 inches by 10 inches, bound in chocolate colored cloth, with the title in gold lettering on side and back. Type and paper are of the finest quality. Price, $5.00, U.S. Cey., £1 1s. 0d. stg., M22., $10.00, Mex. Cey., Frs. 25, postpaid.

Copies of this excellent work may be had from the Book Department of Canaadian Mining Journal, Toronto

FACULTY OF APPLIED SCIENCE AND ENGINEERING

Courses in

1. Civil Engineering.
2. Mining Engineering.
3. Mechanical and Electrical Engineering.
4. Architecture.
5. Analytical and Applied Chemistry.
6. Chemical Engineering.

Diploma granted at the end of three years B. A. Sc. at the end of one additional year.

Professional Degrees:

Civil Engineer (C. E.)
Mining Engineer (M. E.)
Mechanical Engineer (M. E.)
Electrical Engineer (E. E.)
Chemical Engineer (C.E.)

For Calendar and other information apply to the Secretary

A. T. LAING.

School of Mining

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

When answering Advertisements please mention THE CANADIAN MINING JOURNAL

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

RAND Mining and Industrial MACHINERY

Our new compressor catalog is now ready for circulation. This book contains over 100 pages of information of interest to mining and manufacturing men. Among the more important articles is one on the selection of a steam driven compressor. The questions of lubrication, air coolings and regulation are thoroughly dealt with, and all standard machines are listed.

Ask for a copy to be sent with any of the following which interest you.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

THE Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

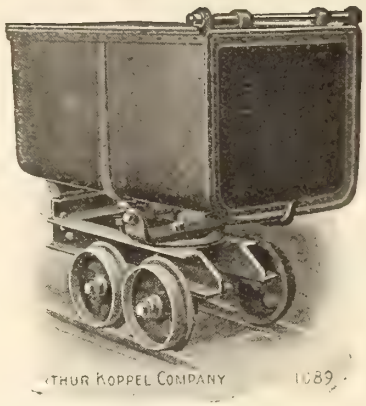
Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

WRITE US FOR DESCRIPTIVE PAMPHLET.



FORWARD SAMPLE OF YOUR ORE FOR PRELIMINARY TEST.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLER

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

MONTREAL TORONTO LONDONDERRY, N.S.

Wrought Iron and Steel Pipes

All Sizes and to any Pressure

Iron and Steel Boiler Tubes

Cold Drawn Seamless Steel Boiler Tubing

"KERVA" BRAND

For Stationary, Marine and Locomotive Boilers

Pressed Steel Floor Plates

Diamond and Ribbed Pattern

BRATTICE CLOTH

Quality Guaranteed. All Sizes for Direct Import

LARGE STOCKS CARRIED IN MONTREAL FOR IMMEDIATE SHIPMENT

WHY IS IT

THAT SALES OF

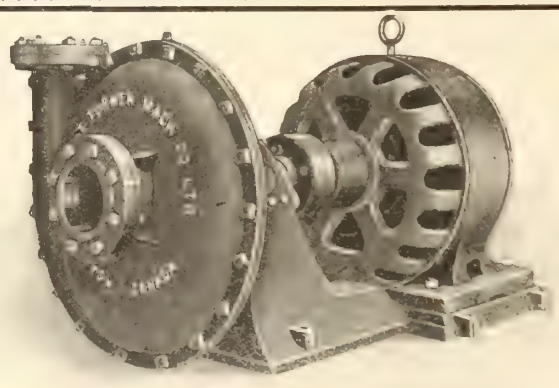
MORTON'S **"B C"**

DRILL STEEL

ARE INCREASING EVERY DAY? MUST BE IT IS BETTER MATERIAL,

Gives Best Satisfaction

AND THE DRILL



LASTS LONGER.

COULD ANYONE EXPECT MORE?

In Stock With

THE CANADIAN MINING JOURNAL

VOL. XXIX. TORONTO, December 1, 1908 No. 23

The Canadian Mining Journal

With which is incorporated the
"CANADIAN MINING REVIEW"
Devoted to Mining, Metallurgy and Allied Industries in Canada
Published fortnightly by the
MINES PUBLISHING CO., LIMITED

Head Office - - Confederation Life Building, Toronto.
Branch Offices Montreal, Halifax, Victoria, and London, Eng.

Editor:
J. C. MURRAY, B.A., B.Sc.

Business Manager:
J. J. HARPELL, B.A.

SUBSCRIPTIONS—Payable in advance, $2.00 a year of 24 numbers, including postage in Canada. In all other countries, including postage, $3.00 a year.

Advertising copy should reach the Toronto Office by the 8th, for the issues of the 15th of each month, and by the 23rd for the issues of the first of the following month. If proof is required, the copy should be sent so that the accepted proof will reach the Toronto Office by the above dates.

CIRCULATION.

During the year ending with March 1st, 1908, 91,750 copies of "The Canadian Mining Journal" were printed and distributed, an average of 3,822 per issue.

"Entered as second-class matter April 23rd, 1908, at the post-office at Buffalo, N.Y., under the Act of Congress of March 3, 1879."

SPECIAL CONTRIBUTORS.

Geology: Dr. Frank D. Adams, McGill University; Dr. A. E. Barlow, late of Geological Survey of Canada; Professor Willett G. Miller, Provincial Geologist of Ontario; Dr. J. E. Woodman, Dalhousie University, Halifax, N.S.

Chemistry: Dr. W. L. Goodwin, Director School of Mining, Kingston, Ontario; Milton Hersey, M.Sc., Official Analyst Province of Quebec.

Mineralogy: Professor W. Nicol, School of Mining, Kingston, Ontario

Mining: S. S. Fowler, M.E., Nelson, B.C.; Frederick Keffer, M.E., Anaconda, B.C.; A. B. Willmott, M.E., Sault Ste. Marie, Ont.; J. C. Gwillim, M.E., School of Mining, Kingston, Ont.; J. Obalski, Inspector of Mines, Quebec; J. Bonsal Porter, M.E., McGill University; H. Mortimer-Lamb, Sec. Can. Min. Inst.; John E. Hardman, M.E., Montreal; Fritz Cirkel, M.E., Montreal; George W. Stuart, M.E., Truro, N.S.

Metallurgy: Stafford F. Kirkpatrick, School of Mining, Kingston, Ontario; A. P. Scott, Dominion Iron & Steel Company, Cape Breton.

Natural Oil and Gas: Eugene Coste, M.E., Toronto, Ont.

MORE ABOUT THE BOOM.

The purchase of shares in recent Cobalt and Montreal River flotations is being indulged in to an extraordinary extent by men of all classes. For their guidance they rely upon brokers and promoters who, in most cases, give nothing for what they receive. In other words, thousands of misguided people are voluntarily handing out their cash to men who not only are totally incompetent to advise, but are ever most anxious to obscure the truth. In short, the eager dupes of newspaper puffs and prospectuses are providing motor-cars, residences, and dropsical bank-accounts for purveyors of engraved paper.

The net results of the present boom can be summed up thus: Some thousands of Canadians will have learned that mines are not made in printing-offices; some dozens of men who should be decorating the interior of our institutions of correction will have acquired wealth; and not a few newspapers, more particularly the Toronto World, will have enjoyed an abnormal revenue from advertising. All of which will react most detrimentally upon genuine mining and honest mining men.

The one outstanding consideration that demands our attention at present is the fact that the promoters of newspaper-advertising schemes have been able to use the names of men who pose as mining experts, but who are known to be ready and willing to sell their approval for a price. To illustrate this it is merely necessary to say that not one of the scores of wild-cats has ventured to employ a mining engineer of good standing. In the nature of things the flowery prospectus and the competent mining engineer cannot mix. And even when a respectable mining engineer has reported favorably on a prospect professional etiquette ensures his silence, and the public is none the wiser.

On the other hand, it is absurdly easy to buy, in open market, the favorable reports of any number of pseudo-experts. And, to lend dignity to the impossible effusions of these prostitutes, it is only necessary to attach the name of a few complaisant and respectable citizens to the list of directors.

Briefly, the gambling that is being carried on in Toronto and Montreal under the name of "mining" can claim no closer kinship to that industry than can Monte Carlo to the Heavenly City. The stock-in-trade for the most profitable confidence-game that modern ingenuity has devised consists in a few acres of land conveniently distant, a striking name, an alleged mining expert, an advertisement in the dailies, a few guinea-pig directors—and there you are!

That such things can and do exist in a community of sane men and women is almost beyond belief. Not

all the blame can be thrown upon those newspapers that have aided and abetted the fakirs. Nor yet upon the Provincial Government can all the responsibility be placed. There rests upon honest mining engineers, mine owners, and upon all connected with what should be the noblest and cleanest of industries, the obligation to give public utterance to their convictions. Further, the Canadian Mining Institute is called upon to throw its influence on the side of right.

But most particularly is it desirable that from our mining schools, from the men who are training the mining engineers of to-morrow, the public should receive a clear pronouncement. The profession of mining engineering requires and must demand protection from pretenders.

WAVERLEY FORTY YEARS AGO.

That indefatigable worker and versatile scientist, Dr. Henry Youle Hind, contributed largely to the literature of this country. His volumes of travel will, perhaps, keep his name green when his other labors shall have been forgotten. But to many his reports on Nova Scotian mining districts are fraught with special interest.

Dr. Hind's report on the Waverley Gold District of Nova Scotia is dated 1869. At that time, except for the use of steam, mining methods in Nova Scotia were crude and primitive. Dr. Hind remarks that on the North or Brodie, lead at Waverley there were then 23 shafts within a distance of only 1,800 feet. The average distance between the shafts was 78 feet; the greatest depth attained was 240 feet; and the mean depth 185 feet. This was also true of the Tudor, North Taylor, South Taylor, and Number VI. leads, on which over a total superficial distance of 4,800 feet, there were no less than 55 shafts. Dr. Hind not only pointed out the futility and wastefulness of a system whereby one shaft was sunk "to every superficial area of forty-seven feet square," but strongly of advised consolidation and co-operation.

He condemned also the practice of mixing quartz from different leads and crushing the whole together. "A poor lead worked at the same cost as a rich lead may neutralize all the benefits which would be obtained if the rich lead were worked alone. Each lead ought to be crushed by itself, and a statement of the result with the cost of mining the quartz recorded. . . . Plans of all the workings are also essential, showing at least monthly progress."

In those days several of the Waverley mines showed, as they do to-day, rich specimen ore. The companies that encountered sufficient quantities began to pay large dividends. Against this Dr. Hind wrote unreservedly. His advice is as necessary to-day as it was forty years ago. "The absorption of all returns to pay large dividends is as a rule as fatal an error in gold mining as in most other enterprises."

The mining costs per ton were extravagant. Dr. Hind states that as Mr. Burkner, operating on the Tudor lead, reported mining expenses of $12 per ton up to the close of 1866. A reduction to $8 per ton was then effected. But at least 33 per cent. of the gold was lost in the tailings.

At one place ten men were employed breaking and feeding 35 tons of quartz to the mill, during 24 hours. "Why should not this work be done by four men feeding a "breaker" with hopper, and moved by the surplus water power?" is the pertinent enquiry of Dr. Hind.

Mr. Burkner's sworn returns for the year 1865 to the Commissioner of Mines show a yield of 8,727 oz. 11 dwt. from 6,972 tons of ore, an average of 1 oz. 6 dwt. per ton. The total working expenses were from $10 to $14 per ton. But the miners levied on the mine, in misappropriating specimens and amalgam, to the surprising extent of "at least $50,000 to $60,000, or 2,500 to 3,000 ounces, if not more!"

There are innumerable passages that, if space permitted, we would quote from Dr. Hind's engaging pamphlet. We have indicated enough, however, to show that there were many factors militating against the continued growth and success of this rich Nova Scotian gold district. Obviously, no gold mines could long survive such treatment as that to which the Waverley mines were subjected.

The mistakes and blunders of the early gold-seekers without doubt have been repeated indefinitely in succeeding years. Probably in the smaller mines and prospects of the province they are being repeated to-day.

As a wonderfully interesting piece of history, and as a clear warning against the errors of ignorant haste and inefficiency, Dr. Hind's "Report on the Waverley Gold District" should be reprinted and distributed throughout the mining sections. At present, copies of the report are becoming more and more rare.

DISCUSSION.

In glancing through the last annual volume of the Journal of the Canadian Mining Institute, a volume, by the way, that outshines those of previous years, we notice a sad dearth of discussion. In themselves the papers are of conspicuous value. Subjects such as the smelting of Cobalt ores, the duties of mining engineers, assaying practice, are of immediate importance. But in every paper there are points that call for discussion. Intelligent, fair discussion is always illuminating. Often it is essential.

Matters of this sort rest primarily with the members of the Institute. First of all, it behooves those who intend to contribute papers to send in their manuscript early in the new year, so that the Secretary may have ample time to get them through the press. Sec-

ondly, those of the members who are able to attend the annual meeting in March should come prepared to exchange views on one or more topics.

The tendency at meetings of technical societies is to forego the reading of papers in their entirety. Usually the author reads a synopsis, and printed copies giving the full text of his paper are distributed. This is a practice that should and must be followed. Time is an all important factor in conventions of busy men. Moreover, listening to a long dissertation that can be perused much more rapidly from the printed page is a weariness to the flesh. It deadens the hearers and leaves little time for debate.

If at all possible—and it will only be possible with the prompt assistance of all intending contributors—each and every paper should be in the Secretary's hands not later than the last of January next.

We may hope then to have advance copies long enough before the annual meeting to ensure complete, lively, and edifying discussions. These, we are sure, will constitute by no means the least instructive portions of the Institute's Journal for 1909.

THE GREAT NORTHERN COAL COMPANY.

The modest province of Nova Scotia has now been included in the wild-cat belt. Under the nurturing care of Dr. Hugo Von Hagen, a lusty member of the species has sprung into life. Its ostensible home is Cumberland County. Its real habitation is in the cultivated cerebellum of the virtuous Von Hagen.

"Roach's Financial Facts," one of those generous guides to wealth and welfare, is published in New York. Its issue of August 15, 1908, is before us. Mr. Henry N. Roach is, apparently, editor and proprietor. Mr. Henry N. Roach is also sole fiscal agent for the "Great Northern Coal Company," and he takes a full page in which to tell of his faith in Von Hagen, and his love of mankind generally. But not one little fact does he impart about the property of the "Great Northern Coal Company." Facts, however, are not necessary. They are in bad taste.

How many shekels would accrue to the exotic Von Hagen and to the revering Roach (was ever man better named!) if they dealt in facts!

Quite between ourselves, Von Hagen's coal mines will never earn a dividend. Nevertheless, such is the skill of this transplanted gentleman, a regular dividend of one per cent. per month is announced in this same issue of "Roach's Financial Facts." And, once more between ourselves, the illustrious Von Hagen deserves so well of his shareholders that he should immediately and for the rest of his natural life be provided with board and lodging at the expense of a grateful nation. There are substantial residences at Dorchester, N.B., and at Kingston, Ont., wherein fitting accommodation is ready. The dear Doctor's modesty should not be permitted to interfere. Indeed he and his only less deserving associates should be given no chance to discuss the matter.

CANADIAN BANKING.

The communications received since our reference to the inadequacy of reserve against Canadian bank notes indicate much misconception on the part of the public concerning these matters.

Subsection 6, Section 65, of the Canadian Bank Act, which deals with the payment of notes of a defunct bank, is as follows:—

"Nothing herein contained shall be construed to impose any liability upon the Government of Canada, or upon the Minister, beyond the amount available from time to time out of the Circulation Fund.

Subsections 3 and 5 of Section 64 states that the Circulation Fund shall be made up by each chartered bank keeping an amount deposited with the Government of Canada equal to 5 per cent. of the average circulation of its noes. (The Act does not specify whether this sum is to be kept in gold, Dominion notes, or ordinary securities.) And, further, that this circulation fund shall continue to be held for the "sole purpose" of redeeming the outstanding notes of any suspended bank.

Subsection 9 of Section 64 reads as follows:—

"The Minister shall, with respect to all notes paid out of the circulation fund, have the same rights as any other holder of the notes of the bank: Provided, that all notes, and all interest thereon, so paid by the Minister, after the amount at the credit of such bank in the Circulation Fund, and all interest due or accruing due thereon, has been exhausted, shall bear interest at a rate of three per centum per annum, from the time such notes and interest are paid until such notes and interest are repaid to the Minister by or out of the assets of such bank."

Thus the Canadian Government takes no responsibility beyond acting as the custodian of this small Circulation Fund. Moreover, this fund, outside of the amount contributed by the defunct bank itself, is in reality nothing more than a source from which a small temporary loan may be had to meet the outstanding notes of the defunct bank. This loan is a first charge on the assets of the bank until it is paid back to the Minister.

To show how inadequate this fund is in amount, it is only necessary to quote the following figures from the last monthly Bank Statement, viz., that for October, 1908:—

Name of Bank.	Notes in circulation.	Deposits with Dom. Gov. for security of note circulation.
Bank of Montreal	$12,417,132	$600,000
Bank of New Brunswick	719,125	35,000
Quebec Bank	1,990 543	87,360
Bank of Nova Scotia	2,972,074	150,110
St. Stephen's Bank	184,790	13,000
Bank of B. N. A.	3,492,547	682,775
Bank of Toronto	3,869,839	160,000
Molsons Bank	3,122,883	145,000
Eastern Townships Bank	2,733,210	123,000
Union Bank of Halifax	1,462,897	75,000
Banque Nationale	2,105,127	90,000
Merchants Bank	4,915,628	240,000
Banque Provincial	1,130,743	45,519
Union Bank of Canada	3,263,293	150,000
Can. Bank of Commerce	9,336,545	450,000
Royal Bank of Canada	3,724,922	190,000
Dominion Bank	3,709,465	160,000
Bank of Hamilton	2,314,447	125,000
Standard Bank	1,423,692	61,000
Banque de St. Jean	14,239	11,427
Banque d'Hochelaga	2,350,906	102,996
Banque de St. Hyacinthe	43,565	16,995
Bank of Ottawa	2,895,895	150,000
Imperial Bank	3,776,027	192,458
Western Bank	504,150	27,005
Traders Bank	2,882,945	148,270
Sovereign Bank	124,420	123,569
Metropolitan Bank	1,124,116	47,200
Home Bank	968,340	35,000
Northern Crown Bank	2,107,790	76,000
Stirling Bank	781,768	33,718
United Empire Bank	177,695	12,000
Farmers' Bank	396,005	15,000
	$83,036,762	$4,574,402

SOUTHEASTERN BRITISH COLUMBIA.

There has hardly been time for a readjustment of the currents that influence the metal markets. An increased demand for silver is confidently expected at an early date. Copper is holding its own, with a tendency towards improvement. The lead market is daily showing renewed strength. For all the metals a rapid recovery—possibly too rapid a recovery—is predicted.

The election of Mr. Taft to the Presidency of the United States has been accepted as indicating that there will be no undue interference with present conditions on the part of the chief executive.

The Canadian elections scarcely left a ripple behind them. In lieu of sharply defined issues, the opposing parties appealed to the country with sentiment and scandal respectively. Sentiment won.

All of which signifies that, whereas a few weeks ago the country was in a state of suspended animation, from now on there will be renewed confidence and widening spheres of activity.

The mines and smelters of Southeastern British Columbia are sensitive to all changes in the prices of metals to a larger extent than obtains in any other section of Canada. It is cheering, therefore, to note that there is a sound economic basis for the vigorous expansion that is reported from Nelson, Sandon, Phoenix, Trail and other centres.

British Columbia has cut its wisdom teeth, and can handle a sanely constructive boom without danger to itself or others.

IRON ORE BOUNTIES.

Mr. James Conmee, M.P., speaking before the Canadian Club of Port Arthur, on Thanksgiving Day, expressed the hope that Canada would develop her vast mineral resources. The iron ore bounties, Mr. Conmee stated, should be fixed upon a sliding scale. He expressed the opinion that the bounties upon products into which foreign ores entered should gradually be wiped out, leaving those on Canadian ores still in effect.

Some such plan as this has much to recommend it. The bounties will have accomplished little good if they do not lead to the development of our own iron ore deposits.

EDITORIAL NOTES.

The tailings wheel will probably be superseded on the Rand by a tailings elevator.

British Columbia can safely boast of a scarcity of wildcat mining schemes. In her day she has had not a few. Now, however, with her mining and smelting enterprises largely under competent and responsible technical men, the howl of the feline is scarcely heard.

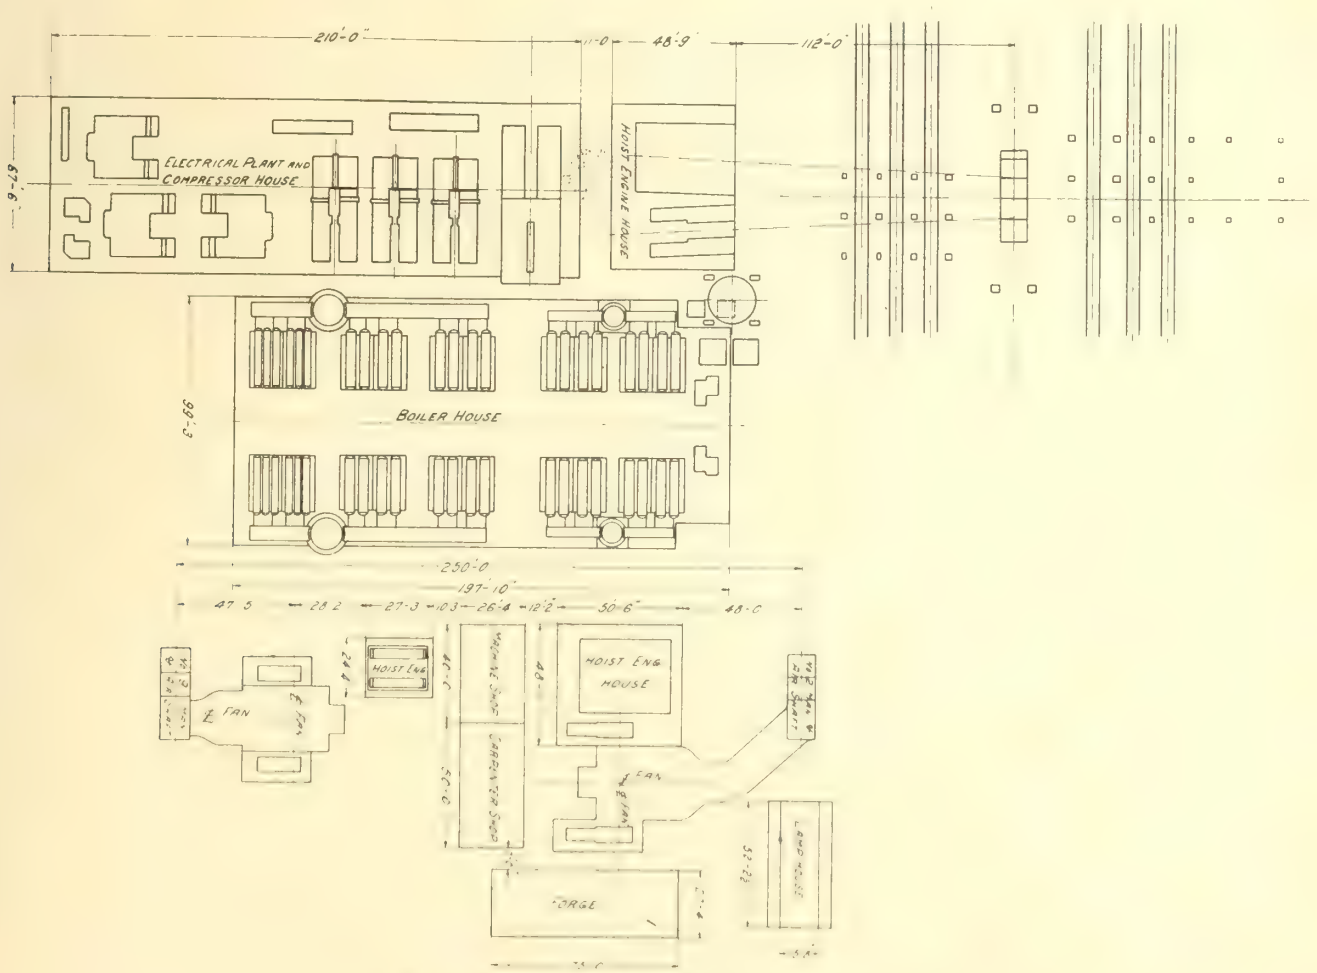
During the first eight months of the year 1907, the British Columbia Copper Company completed 3,667 feet of diamond drilling. In the month of March the average cost per foot reached the low figure of $1.045. In that month 540 feet were drilled in ore and lime rock, 200 vertical, 340 horizontal. The ore and some of the limstones were medium hard. Electric power was used.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

By F. W. Gray.

(Continued from last issue.)

Dominion No. 2 Colliery.



Dominion No. 2 is justly regarded as the show place among the Dominion Coal Company's collieries. It involved a very large capital expenditure, and everything was designed on a large and elaborate scale. Its central position has tended to emphasize its general importance, and successive accretions such as the Central Electric Plant, the Central Horse Hospital, and the Central Rescue Station have added to its growth from year to year. It is a cardinal article of belief in Glace Bay that Number Two is the largest colliery in the world.

Two seams are worked here, the Harbor and the Phalen. The same shaft opening and surface erections serve for the two seams. This description will deal with the whole colliery, excepting only the workings of No. 9—the Harbor seam—which will be referred to when considering the Harbor seam generally.

The hoisting shaft was sunk exactly on the outcrop of the pavement of the Hub seam. The following section gives actual measurements down to the Phalen pavement; below that the figures given are estimated from the best available data:—

	Coal and Measures. Feet.	Total Depth. Feet.
Hub Seam	9.6	
	404.6	
Harbour Seam	5.6	410.0
	253.3	
Boutilier Seam	3.9	667.0
	73.5	
Back Pit	2.7	743.0
	115.6	
Phalen Seam	8.6	867.0
	160.0	
Emery Seam	4.6	1,031.0
	91.0	
Small seam (McRury?).....	2.0	1,124.0
	209.0	
Lorway Seam	4.6	1,137.0

Below the Lorway or Gardiner seam lie at least three other workable seams, shown on the geological map as the Clarke, Martin and Mullins seams. Their

Plan V.—Dominion No. 2 Colliery. General Surface Lay-out.

positions and value are not, however, fully proven, and it will not be until the thicker and more profitable seams of the Sydney coal field are worked out that much attention will be paid to the lower seams. Neglecting these lower seams, however, there are at least seven workable seams of coal from the Hub to the Lorway, all easily accessible, giving an aggregate thickness of nearly forty feet of coal in the comparatively shallow depth of 1,200 feet.

The seams are so spaced that they can be worked without seriously interfering with each other, if the workings are properly laid out and ordinary precautions are taken. It is to be expected that the section shown at this point is largely that which will be found under the vast submarine areas lying off Table Head.

The shafts of No. 2 were sunk at a point where the regular contours of the Glace Bay Basin begin to be influenced by the turning up of the measures towards the Bridgeport anticline. The axis of the trough is about 1,000 feet to the north of the shafts, and indications are that the axis runs parallel to the line of the anticline and proceeds out to sea in a direction almost due east.

The sinking of the shafts was commenced in October, 1899. The Phalen seam was reached in the following June, and the regular hoisting of coal dates from 1902, since which time the Phalen seam has produced three and one-half million tons. The present monthly output is 70,000 tons, and 3,221 tons have been hoisted from the Phalen seam in one day. The largest tonnage obtained in one day from both the seams was 5,1000 tons. The territory at present allotted to No. 2 will give an ouput of 800,000 tons per annum for a period of over fifty years from the Phalen seam.

Plan A will give a general idea of the surface layout and the extent of the equipment.

The power plant consists of 20 Babcock & Wilcox boilers, rated at 6,360 horsepower. They are fired by Jones's underfeed stokers, which are fed by hand at the present time. It is probable that a coal-handling plant may be erected at a future date. The forced draft is obtained from two 8-foot Sturtevant blowing fans. The two large smokestacks are of steel, 70 feet and 75 feet high, 9 and 10 feet diameter, respectively.

The motive power for underground use is entirely compressed air, and the compressing plant is a very large one. The compressor house is of steel frame construction with walls of concrete and expanded metal. An addition was built in 1906 to house the Central Electric Plant, which will be later referred to. The new portion of the building is of steel frame and brick construction. The whole building is 210 feet long by 67 feet 6 inches wide, and 30 feet high.

The air compressors in the building are as follows:

One Walker compound compressor, steam cylinders 31 by 57 inches, air cylinders 32 to 51 inches, stroke 60 inches, capacity 3,000 cubic feet per minute.

Three Rand compressors, compound, steam cylinders 36 by 20 inches, air 32 by 20 inches, stroke 48 inches, each delivering 3,000 cubic feet per minute.

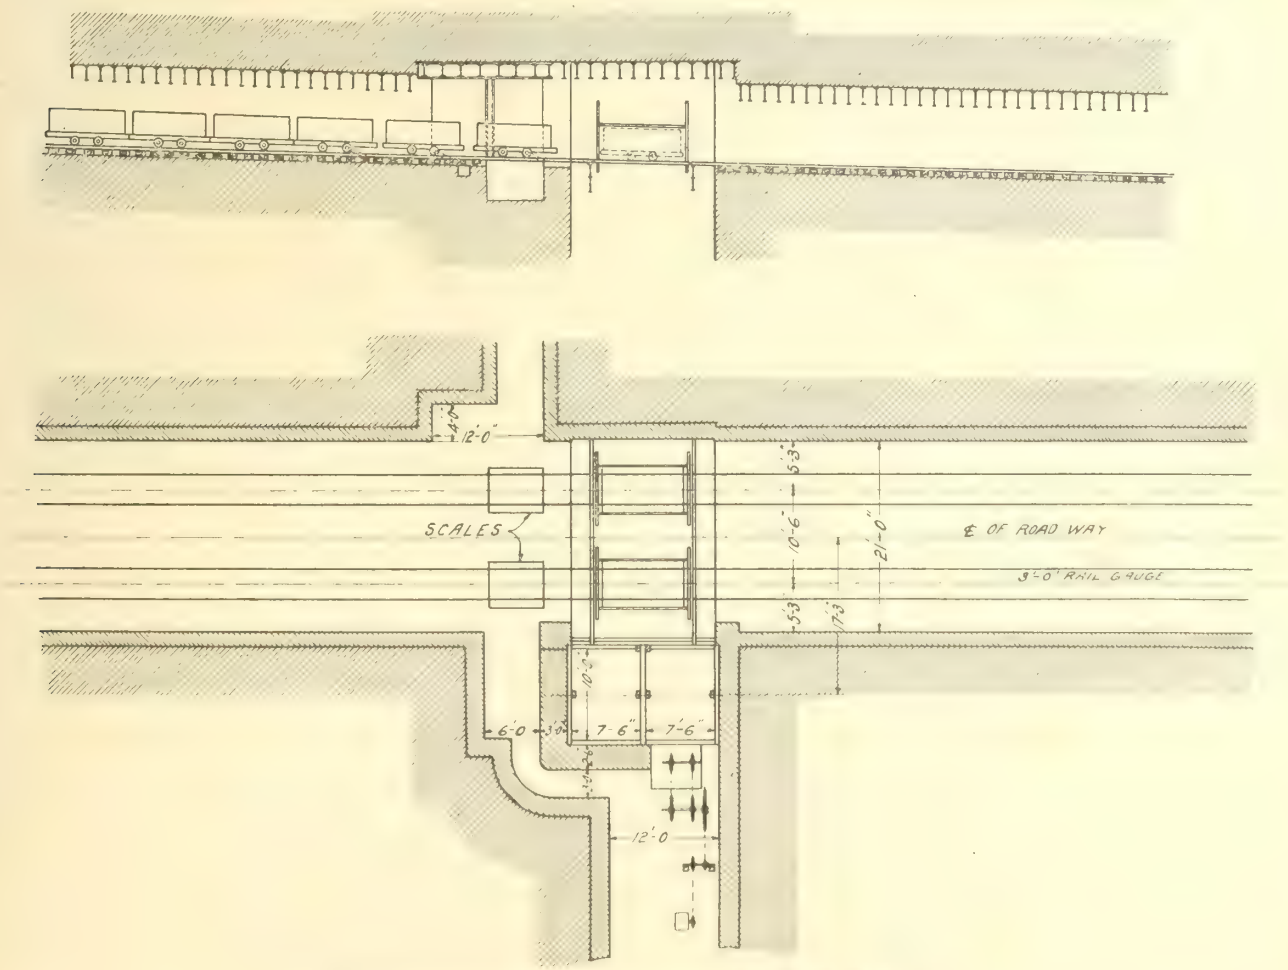
Two straight-line Norwalk compressors.

Dominion No. 2.

The total air compressing capacity is about 16,000 cubic feet per minute.

The bankhead is a large structure, 120 feet high to the top of the tower and 132 feet to the centre line of the pulley axle. It is constructed entirely of steel on concrete foundations, and is of exceedingly stiff and rigid design. It is covered with corrugated iron, which has deteriorated rapidly under the influence of the weather and sea air, but the actual structure of the bankhead itself is in excellent repair, and it is said to vibrate less than any of the other bankheads.

The Phalen hoisting engine is a 34 by 48 inch horizontal double engine, with slide valves, made by the Dixon Co., Pennsylvania. The hoisting drum is 10 feet 4 inches in diameter by 5 feet 7 inches on the face. The hoisting rope is 1⅝ inches in diameter, passing overhead pulleys 12 feet in diameter. These pulleys have 36 spokes 13⅛ inches in diameter. The axle is 9½ inches in diameter.



The Harbour hoisting engine is a 24 by 42 inch horizontal double engine with Corliss valve gear, made by the Jenckes Co. The rope is 1⅜ inches in diameter, and the hoisting drum 8 feet in diameter by 6 feet 4 inches.

Both these engines are housed in one building, built of steel framework and reinforced concrete, like the compressor house.

The hoisting arrangements are very interesting, particularly those for the Phalen side. The main hoisting shaft is 11 feet by 37 feet over all, divided into five compartments, two for the Harbour, two for the Phalen, and one for a pipe compartment.

The coal is brought to the shaft bottom in tubs of 2 tons capacity. It is weighed in the bottom (see Plan B), and the tubs run by gravity into the tipples, which are operated by compressed air. The tipples dump the coal into two storage chutes (see Plan C), which are so arranged by means of doors that the coal from either tipple can be put into either chute. The chutes have an inclination of 50 degrees, and the coal is retained in the chute by a swinging door fastened by a spring latch. The door is actually kept in the closed position by a counterweight passing over a pulley, the shaft of the pulley forming the hinge of the door. The counterweight is attached to a chain passing over the pulley and drawn tight across the shaft bottom, in such a position that when the cage descends the lower framework impinges upon the taut chain and draws down the door of the storage chute, which then becomes a continuation of the chute, over which its contents are discharged into the hoisting tank. By means of the lever arrangement shown, the spring latch is released by the descending cage some little time before the bottom of the cage touches the chain which operates the storage chute door.

The hoisting tank is a boxlike receptacle, with an inclined floor mounted on a pivoted framework arranged like the ordinary self-dumping cage. There are two sets of guide spears for the hoisting tank, one for the main side shoes attached to the outer framework of the arrangement, and a smaller set of spears which pass between roller guides attached to the tank itself, and serve to keep the tank from dumping should the lock slip in transit. On reaching the top the lock of the tank is released by a catch, and the tank lunges forward, tightening the side chains and opening the door of the tank, automatically discharging the contents on to the screens. The hoisting tank has a capacity of between 7 and 8 tons, but the normal load is 6 tons. The tank and framework weigh about 10 tons, which, added to the weight of the coal being hoisted, gives a total dead weight on the rope of about 16 tons. The entire arrangement is automatic from the time the tubs leave the scale to the operation of discharging the coal on the screens. Any coal that falls from the chute drops to the bottom of the shaft, and is there lifted by a bucket conveyor to the level of the pit bottom, where it is reloaded into tubs. This dropped coal does not amount to more than four tons per day.

Plan B—Plan and Elevation of Dominion No. 2 (Phalen) Pit Bottom

The hoisting arrangements of the Harbour seam consist of the ordinary self-dumping cage, and are similar to those already described at other collieries.

As the hoisting shaft is used exclusively for coal, two man shafts are provided for the two seams. Each of the man shafts serves both for the conveyance of men and for ventilating purposes, being divided into three compartments, namely, two for hoisting and one for intake air. All the hoisting shafts are used for the upcast air, in accordance with the usual pretice here. The heated upcast air prevents the formation of ice during the winter months, which would otherwise interfere very seriously with the operations. The hoisting engine of the Phalen man shaft is of the same design as the coal hoist, before described. The Harbour man hoist is a horizontal double engine 18 by 26 inch, with slide valves, made by Matheson, of New Glasgow.

The workings are ventilated by two fans; one for each seam. The Phalen fan is a Walker fan, 24 ft. dia. by 8 ft. 6 inch. across the face of the vanes. It has a rated capacity of 350,000 cub. ft. per min. at 3 inch W.G. It is cased in brick and is directly connected to a horizontal engine 20 by 42 inch., which is contained in the same engine house as the hoisting engine for the Phalen man shaft. On the other side of the fan is a brick house containing a duplicate engine as an auxiliary in case of breakdown. The Harbour fan is of similar capacity, of the Guibal type, and is cased in steel. It is directly connected to two engines, one of which is in use, the other being reserved for emergencies.

Among other surface erections are the following:

The lamphouse is 52 feet long, and has a concrete floor. It contains 1,700 safety lamps, all of the A. & B. type, with the necessary cleaning, filling and igniting apparatus.

There are also large machine, blacksmith and carpenter shops, similar to those at other collieries already described.

Some little distance away from the main buildings is the Wash House, which contains 66 lockers and is the largest of the company's wash houses. It is 120 feet long by 30 feet wide.

The whole of the motive power used underground is compressed air, and all the coal is cut with the ordinary "puncher" machines.

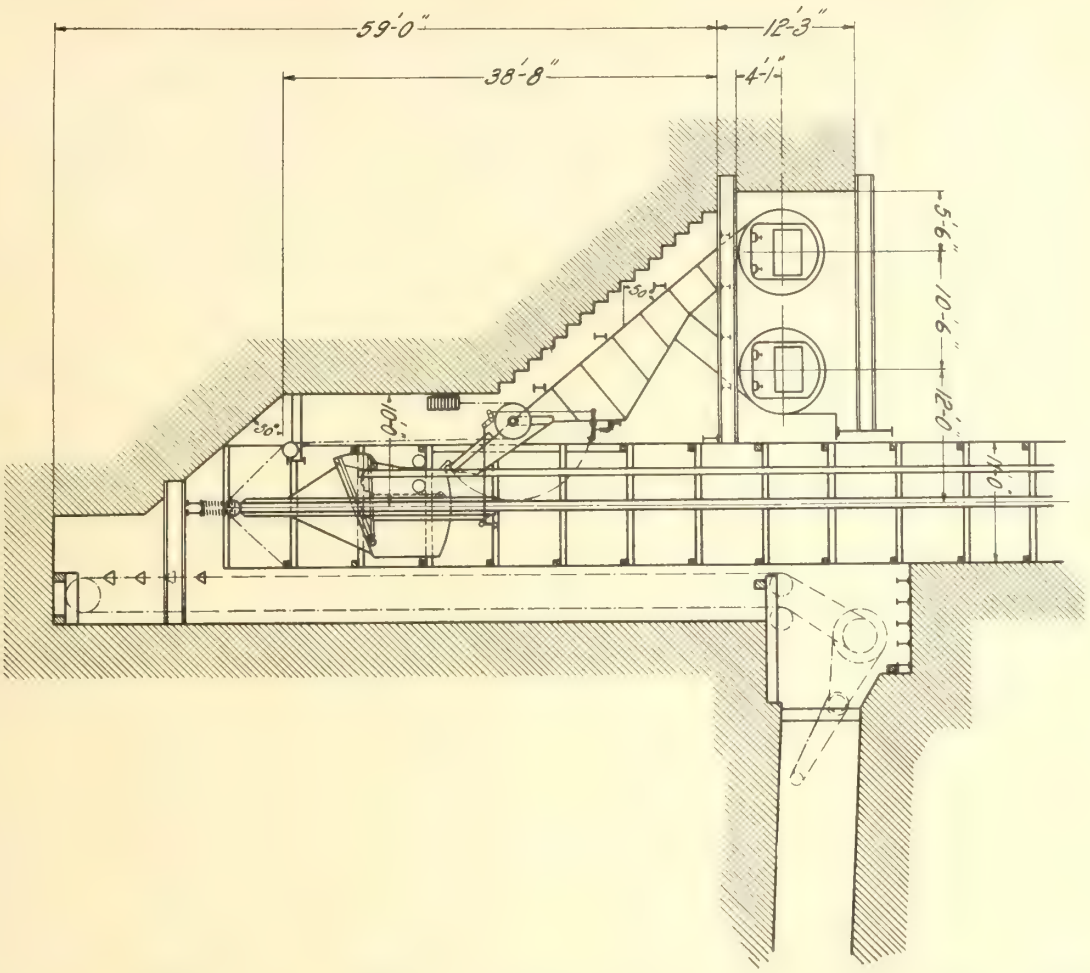
Dominion No. 2

No. 2 is the only one of the coal company's mines which uses compressed aid locomotives for haulage purposes. The following is a list of the locomotives in operation at the present time:

No.	Mkr.	No. of whls.	Wght.	Cylinders.	Length.
1	Porter	Four	7 tons	7" x12"	13 ft.
1	Porter	Four	10 tons	7" x14"	18 ft.
3	Porter	Four	15 tons	10½"x14"	19 ft.
1	Baldwin	Six	17 tons	11" x14"	20 ft.
1	Baldwin	Six	20 tons	11" x14"	23 ft.

The mine cars in use have a capacity of 2 tons. The gauge is 3 ft. 0 inch, and a 56 lb. rail is used on the motor roads, which have to be very solidly laid and ballasted.

The main pit bottom extends for a distance of 200 feet on the empty side of the shaft, and for a distance of 300 feet on the full side. Over the whole of this 500 feet the sides are concreted, the walls averaging 1 ft. 6 inch. in thickness. The roof is supported by I beams. 24 inch. by 25 ft. span, spaced with from 1 ft. 6 inch. to 4 ft. 0 inch. centres.



The air mains are so arranged that they can be used as water mains. Owing to the depth of No. 2, the Phalen seam is fairly dry and the heavy system of haulage in use there tends to create fine dust on the haulage ways. Every precaution is used to lessen the amount of dust, and the amount is periodically sprayed with water, more frequently in the winter months than in the summer months, owing to the greater dryness of the air in winter. In some sections the dust is swept up and taken out of the mine altogether to be used at the fires. "Permitted explosives" are used exclusively, and wherever gas is reported the firing of shots is discontinud until the place is reported clear.

The mine employs about 100 horses, and has a force of a little less than 1,000 men.

Outside the colliery fence is the Central Rescue Station, elsewhere referred to, and the Firemen's Hall. The men of No. 2 and 9 collieries have taken up the work of training in the use of the Draeger apparatus with a good deal of enthusiasm, and they were well represented in the contingent that were sent over to Sydney Mines. In striking contrast to all the modern appliances at No. 2 we noticed near the Compressor House an old Shand & Mason manual fire engine, which looked as though it had strayed from some museum of antiquities.

The town of New Aberdeen is owned by the Coal Company, who have about 730 houses at this place, including the houses of the men employed at the Hub Colliery. There are also two large boarding houses owned by the company. For a good many reasons the population near No. 2 is more cosmopolitan than at the other mines, and in addition to the native and British element one can find Germans, Poles, Hungarians, Italians, Russians, Belgians, and Frenchmen, many of whom are old residents at New Aberdeen.

Central Electric Plant.—In 1906 an addition was made to the Compressor House for the housing of a central electric generator station. There are three generating units, consisting of a Westinghouse Alternator, 550 K.W., 25 cycle, 3 phase, 125 revolutions per minute, 6,600 volts, directly coupled to a compound Goldie-McCulloch horizontal engine of 700 I.H.P. The high pressure cylinder is 20 inches, low pressure engine 40 inches, stroke 26 inches. The fly-wheel is 14 feet in diameter and weighs 60,000 lbs. The extension is arranged to admit of another unit when required. There are two exciters made by the Westinghouse Company, 75 K.W., directly connected to 12 x 12 Ideal engines. The switch-board is of black marble, eight panels. The power generated at this station is used for pumping purposes, for driving screen machinery and for colliery lighting. It is also used for driving the machinery in the Central Shops at Glace Bay. The transmission line poles are 35 ft. high, spaced not more than 100 ft apart. The wire used is 4 in. x 0 in., of bare hard-drawn copper. The drop in voltage experienced is about 5 per cent.

Plan C—Dominion No. 2 Colliery. Sketch of the Hoisting arrangements on the Phalen Seam, showing Tipples, Storage Chutes, Hoisting Tank, and Guide Spears

The transformer houses at the collieries are built of hollow glazed earthenware blocks. A typical house is 13 feet high by 23 feet long and 17 feet wide. The roof is made four ply, 1¼ inch T. & G. covered with tar and gravel, sloping. Each house contains three 75 K.W. Westinghouse transformers, rated 3800/317 volts. The boreholes for the conveyance of electric current are drilled 9 inches diameter, cased to 6 inches. The cable for borehole transmission is usually No. 4-0 lead covered paper insulated cable.

Central Horse Hospital.—Near No. 2 Colliery is situated also the Central Horse Hospital. This building is under the charge of the veterinary surgeon of the Coal Company, who is responsible for the care of the Coal Company's horses, which number between six and seven hundred, according to the season of the year. The building contains stalls for eighteen horses, and is fitted with concrete bath for the treatment of diseased animals, and all the modern appliances for veterinary surgery. A shoeing shop is close by, where all cases of special or pathological shoeing are done under the direction of the veterinary surgeon. The veterinary surgeon also keeps his stock of horse medicine here, and it is used as a general distributing centre.

LABORATORY ROUTINE IN MODERN COPPER SMELTERS

Paper read before the Institute of Mining and Metallurgy

By H. T. Waller, Member.

The following brief description of some of the laboratory methods which the author has found most useful in connection with copper blast furnace smelting may, it is hoped, be of interest to members of this Institution. They do not by any means cover the whole of the work which the smelter chemist may be called on to do, which is, of course, extended over a very wide field. They deal, however, with the determinations which will constitute the bulk of his work at all times, and which will, owing to the volume of work and speed required, probably cause him the most anxiety at first.

What may be called the daily routine work of the smelter chemist consists in making more or less complete analyses of such samples of ores, fluxes and furnace products as may be required for the immediate use of the superintendent in charge. He will have to determine, at least daily, and sometimes more often, the principal constituents of the slag, and make frequent

determinations of copper in the matte produced by each furnace, besides making endless determinations of copper, silica, iron, lime, sulphur, zinc, etc., in ores, briquettes, flue dust, etc.

In the following scheme the analysis of slags has been considered first, as characteristic of the rest of the work. Except in special cases ½ grm. is always taken for analysis, and standard solutions are made up so that 1 cc.=1% of the substance to be determined on the ½ grm basis.

Analysis of Slags.—Copper slags, which have been properly chilled and crushed to 100 mesh, can be completely dissolved in dilute HCl when the silica is not above 40 to 45%. Only those samples which have cooled slowly and crystallised, like those taken from the dump, or those which are very highly silicious, will require fusion with alkalies for their decomposition.

Slag is sampled at the furnace by dipping a small iron rod into the stream of slag as it flows from the settler, and plunging the rod immediately into a bucket of water, or by catching some of the slag in a small iron ladle and pouring it into the water. A sample is generally thus taken every hour from each furnace. The buckets in which the samples are collected must be provided with well-fitting covers and should be kept covered as much as possible, or the sample will certainly be contaminated by splashes of matte or other cupriferous matter.

Slag which has been chilled in water is entirely different in appearance from that which has cooled slowly. It is perfectly amorphous throughout and very brittle, with a shiny conchoidal fracture. Badly-chilled slag can often be detected by its dull appearance even when finely powdered. As a regular thing the slag is analysed every 12 or 24 hours for copper, silica, iron, lime, and less frequently for zinc, sulphur, alumina and other constituents.

These determinations may be made for five or six furnaces in about two hours in a well-arranged laboratory, the chief requirements of which are, a good hearth or hot plate under a hood of fume cupboard, an arrangement for cooling flasks, beakers, etc., in running water, several Dangler blast lamps, or their equivalent, for fusions and ignition of precipitates and a row of filter flasks connected to a vacuum filter pump. For a convenient hot water supply one or two large copper tea kettles can hardly be surpassed.

Determination of Copper.—The copper present in blast furnace slags is seldom less than 0.1% or more than 0.8%. It may be determined colorimetrically as follows:—2 grm. of slag are placed in a small beaker and 50 cc. of hot water added; 15 cc. HCl are added at once while the slag is kept in suspension by vigorous stirring. Practically all the SiO_2, Fe, CaO, etc., is dissolved and can be filtered off from the black residue, which consists of copper sulphide and a little partly decomposed slag and matte.

The solution always smells strongly of H_2S, which ensures that the copper will remain insoluble. It cannot be depended on to filter quickly unless a filter pump is used, as there is often unavoidably a slight separation of gelatinous silica. The paper is ignited thoroughly in a Berlin crucible, no organic matter being allowed to remain or it will give the final copper solution a grenish tint which renders the determination worthless.

The residue is brushed into a beaker, 5 cc. HNO_3, and a few drops of HCl are added and boiled till red fumes cease to come off. It is diluted, 20 cc. of ammonia are added, boiled and filtered into a colorimetric bottle. A double precipitation with ammonia is not necessary, as the amount of iron to be separated is very small and does not carry down appreciable amounts of copper. The iron present at this stage is derived, as also is most of the copper, chiefly from shots of matte which have been included in the slag.

The standard colorimetric bottles are generally made up about once a month. They do not alter appreciably in color over a much longer period, but the ammonia attacks the glass, forming a flaky precipitate which if shaken up in moving the bottles about will cloud the solution. They are quickly renewed at any time as follows:—

0.5 grm. of copper is dissolved in a little HNO_3, the red fumes are boiled off and it is diluted to 500 cc. 10 colorimetric bottles are taken, labelled 0.1, 0.2, 0.3, etc. 5 cc. of HNO_3 are added to each, then diluted, and from a burette 1 cc. of the above solution is added to the first, 2 cc. to the second, and an additional 1 cc. to each successive bottle. 20 cc. of ammonia are added to each bottle, after which they are filled with water up to the bottoms of the labels, which are placed at the same level, so that the bottles contain about 150 cc. of solution.

The bottles are placed on a level with the eye on a narrow shelf covered and backed with white paper or tiles. It is very important that there should be only one source of light, and that it should be directly behind the observer when comparing colors. There should be space enough on the shelf between the standard bottles to allow of introducing the bottle to be tested, which is moved along till its place in the series is determined.

Since 2 grm. of slag have been taken, the fraction on the bottle corresponding divided by two will give the required percentage of copper in the slag.

A useful exercise for anyone employing this method for the first time is to place the bottles on the shelf so that the labels cannot be seen, and then to move them about at random, until the original order is destroyed. When the beginner finds that he can replace the bottles in their proper order with certainty, without looking at the labels, he will have considerable confidence in his results.

This method is very rapid, a batch of six samples being easily done in half an hour or so, the chief delay being in igniting and cooling the porcelain crucibles. The results are excellent, for though an individual determination may perhaps be 5-100 of a per cent. out through difficulty in exactly comparing the colors, the average result will be very much closer than this, as may be proved by making a composite sample of the slags done, say once a month, and determining the copper on the battery, or by some other more exact method.

Probably the only serious rival to the method given above, for separating the copper from slag, is that in which the silica is volatilised by evaporation with hydrofluoric acid.

This method has the advantage that it can be used on slags which are insoluable in HCl. It is, however, a somewhat tedious process, and necessitates the use of a re-agent, which few will care to employ if it can possibly be avoided. Then, of course, the hydrofluoric acid treatment still leaves the copper to be separated from the iron by some other means. The method here given is indeed unique in the facility with which the copper is at once separated from large amounts of iron and silica.

Determination of Iron.—The bichromate method serves all purposes for iron determination. The end reaction is quite sharp and decisive in practised hands, though, perhaps, a little tedious, which fact has led some to prefer the permanganate titration; but the great advantages in speed and reliability which the method possesses over all others entirely counterbalance this defect. 0.5 grm. of slag is placed in a beaker, 25 cc. of boiling water are added. The beaker is placed on a hot plate and stirred vigorously to keep the slag in suspension while 20 cc. of strong HCl is being added.

It is stirred till there is no longer of gelatinised slag sticking to the bottom of the beaker, and boiled for a few minutes to remove H_2S. While still hot two or three drops of $SnCl_2$ solution are added until the solution is colorless, then an extra drop or two are added, and the beaker is cooled rapidly by standing in running water. It must not be allowed to stand longer than necessary, as, when cold, the iron will oxidise even in the presence of an excess of tin chloride.

When cold, 20 cc. of saturated $HgCl_2$ solution are added, and after alowing to stand about a minute it is titrated with $K_2Cr_2O_7$. The mercuric chloride solution should produce a beautiful silky precipitate. If the precipitate is dense or heavy it shows that an unnecessary amount of tin chloride has been added. The whole determination can be done in ten minutes.

The tin chloride solution required for reduction will keep well if made up as follows:—1 lb. of stannous chloride is dissolved in 500 cc. of HCl and diluted gradually up to 2 litres. A small quantity is kept for use on the bench in a 2-oz. Schuster dropping bottle. The potassium ferricyanide indicator should be quite dilute, 0.1 grm. of the salt being sufficient for a 2-oz. Schuster bottle, in which the solution will keep well for a week or more.

The standard solution contains 4.392 grm. of $K_2Cr_2O_7$ per litre. It is standardised against pure iron wire by dissolving in HCl, reducing with $SnCl_2$, and treating as above described. 1 cc. of the solution= 0.005 grm. of iron, or 1% where 0.5 grm. of slag is taken.

Determination of Silica.—0.5 grm. of slag is moistened with about 20 drops of water in the bottom of a 3½-in. casserole. 5 cc. of HCl are added, while the slag is kept rubbed up with a short flat-topped glass rod, the casserole being placed on the hot plate and heated while stirring all the time until the silica belatinisies. This takes place in about half a minute, when the casserole with the rod in it is taken to complete dryness.

A perfectly safe and rapid way of evaporating to dryness in an open casserole, is to place it on a ring which supports the casserole just above but not touching the hot plate, while it keeps the sides of the casserole surrounded by very hot air.

Excellent rings can be made by cutting a round hole in the botttom of the small tin dishes which are often supplied for drying samples, or they can be made in the form of a short truncated cone of tin plate. It is convenient to have a dozen or more of these evaporating rings, as they are useful in many determinations.

When nearly dry, and there is no more danger of spitting, the lumps of gelatinised matter may be broken up with the rod, and the casserole placed directly on the hot plate until all sign of HCl fumes has disappeared. The residue, after cooling, is moistened with 5 cc. of HCl, a few drops of HNO_2 are added, it is diluted with hot water filtered with the aid of a filter pump, ignited and weighed.

Determination of Lime.—Lime is determined in the filtrate from the silica as follows:—The filtrate is transferred to a beaker heated to nearly boiling, a decided excess of ammonia is added, then solid oxalic acid is added from a teaspoon, stirring until the ferric hydrate has all dissolved. Ammonia is added again till there is a slight permanent precipitate of ferric hydrate, and the solution again cleared by the careful addition of small quantities of oxalic acid. It is boiled and filtered. The filter and precipitate is placed in a beaker containing 10 cc. of H_2SO_4, which has been diluted, first with a little cold water, and then with 100 cc. of boiling water. It is titrated at once with standard potassium permanganate solution, of which 1 cc.=0.005 grm. CaO, or 1% CaO when ½ grm. of sample has been taken. The standard solution contains 5.991 grm. of $KMnO_4$ per litre.

To standardise with oxalic acid, a few crystals between 0.1 and 0.2 grm. of oxalic acid are weighed out and dissolved in a beaker of hot dilute H_2SO_4, as was the calcium oxalate precipitate, and titrated at once in a similar manner. The weight of the oxalic acid taken x0.444 gives the equivalent weight of CaO.

Standardisation with metallic iron should be made at least as a check on a new bottle of oxalic acid. In which case $\frac{Fe}{2}$ = CaO.

Determination of Al_2O_3.—This is best done by direct weighing as phosphote, the method is practically as given by Blair for iron ores.

0.5 grm. of slag is taken and treated exactly as in silica determination until the silica has been separated and filtered off. The alumina, together with the iron, which must be in the ferric condition, is thus obtained in a hydrochloric acid solution. To the solution, which should occpy about 100 cc., 15 cc. of a saturated solution of microcosmic salt are added, and it is carefully neutralised with ammonia until a slight permanent white precipitate is obtained.

It is heated to boiling and carefully acidulated with HCl until the solution has cleared, taking care not to have more than about 2 cc. of HCl in excess, 25 cc. of a saturated solution of sodium thiosulphate are added, and 5 cc. of glacial acetic acid, or an equivalent amount of dilute acetic acid. The solution is now boiled for ten minutes, when a white precipitate which is easily filtered and washed, and consists of aluminium phosphate with sulphur, is obtained.

It is filtered over a filter pump, dried and ignited with its filter paper. It must be ignited very gently at first until the paper and sulphur are burned off, being finally brought to a bright red heat. The ignited precipitate is perfectly white and tender, and should show no signs of fusion. It consists of Al_3PO_4 and its weight in grm. x 84 gives the percentage of Al_2O_3 when ½ grm. of sample has been taken.

Determination of Zinc.—The method of Messrs. Von Schultz and Lowe, or its modifications, seem to be used almost universally for the determination of zinc in copper smelting.

0.5 grm. of slag is treated as in silica determination until the gelatinous silica is dehydrated. 20 cc. of a saturated solution of $KClO_3$ in nitric acid are added to the casserole, which is covered with a clock glass and taken to complete dryness on the hot plate. Just before solidification takes place the cover may be removed, drained, and left leaning up against the casserole, which is placed on an evaporating ring until all is dry. This prevents matter from spitting up and sticking to the clock glass, which would afterwards be a little troublesome to remove.

The main object of the powerfully oxidising chlorate mixture is to convert manganese into black oxide, which is insoluble during the subsequent treatment. To the residue in the casserole are now added 7 grm. of solid ammonium chloride, 20 cc. of ammonia, and 25 cc. of hot water in succession. The residue is now well rubbed with a rubber-topped glass rod until loosened from the casserole, and disintegrated and dissolved as much as possible. It is finally covered, and boiled for one minute and filtered.

The ferric hydrate thus obtained is in a very compact and granular form, and will carry down with it much less zinc than when precipitated out of solution in the ordinary way. It is, however, impossible to remove all the zinc in one operation if much iron is present, so if great accuracy is required the residue should be washed from the paper with a little water back into the casserole, evaporated to dryness, again treated with the chlorate mixture, reprecipitated exactly as before, and the two filtrates combined for further treatment. If copper is present, as shown by the blue color of the ammoniacal filtrate, HCl is added carefully until the color has just disappeared. If not, the neutralization is effected with the aid of litmus paper.

In either case 10 cc. excess HCl is added. If copper is present, about 20 grm. of granulated lead are added, and the solution boiled for about five minutes, when the solution will be colorless, and all the copper precipitated. Instead of granulated lead a few pieces of test lead foil will do equally well.

The lead and copper need not be removed from the solution, which is now ready for titration.

The solution should occupy about 75 cc., and should be titrated at about 70° C.

The standard solution contains 22.5 grm. of $K_4Fe(CN)_6$ per litre. 1 cc.=0.005 grm. zinc.

To standardise the solution about 0.1 grm. of zinc oxide is weighed out, or, better still, an amount approximately equivalent to the amount of zinc in the portion of ore taken. The zinc oxide is dissolved in 10 cc. of HCl, and diluted to 75 cc. with hot water and titrated. The indicator, which is kept in a Schuster bottle for use on the spot plate, is an almost saturated solution of uranium nitrate.

Determination of Sulphur.—Sulphur is always weighed as $BaSO_4$. 0.5 grm. of slag is treated in a covered casserole with 10 cc. of strong nitric acid, warming gently, and adding from time to time a few crystals of $KClO_3$. When all action has ceased the casserole is placed on an evaporating ring and taken nearly to dryness. 10 cc. of HCl are then added and taken to complete dryness to render the silica insoluble. It is finally taken up with hydrochloric acid, diluted with hot water, and filtered.

The filtrate is made alkaline with ammonia, and about 3 grm. of barium chloride are added. It is boiled for a few minutes, acidulated with HCl to re-dissolve the iron, again boiled for several minutes and allowed to settle well before filtering.

Barium sulphate can in this way be separated in one operation from solutions containing large quantities of iron without contamination with the latter metal, as the iron is thrown out of solution before the precipitation takes place. With a reasonable degree of washing the ignited precipitate of $BaSO_4$ should be perfectly white and free from iron. The weight of the precipitate x 27.5 gives the percentage of sudphur when ½ grm. of sample has been taken.

Analysis of Ores and Fluxes.—Under this head are considered the determinations which have to be made on the various samples of ores, etc., about to be smelted or which it is proposed to purchase. The following substances have to be determined, if present, practically in everything that goes into the furnace: copper, silia, iron, lime, sulphur and zinc. Alumina is only required when present in considerable quantity (5% or more). It is weighed with and counted as silica under ordinary circumstances, the matter insoluable in acids being generally reported as "silica." The alumina will be determined, occasionally, in the ore from certain localities to enable a deduction to be made for it from silicia in calculating furnace charges.

Determination of Copper.—The cyanide method as given below may be used for ores, matte, fluedust, etc.

1 grm. of ore or 0.5 grm. of matte is heated in a small covered beaker with 10 cc. of nitric acid. In the case of fluedust, samples or those containing oxide of iron, a little HCl should be added to assist solution.

When action has apparently ceased, 10 cc. of H_2SO_4 are added and boiled till all the nitric acid has evaporated.

It is not sufficient to boil until heavy white fumes of sulphuric acid appear. The white fumes should be seen to come off freely for at least 10 minutes, or there is danger of considerable HNO_3 remaining in the solution. Very little of the H_2SO_4 actually boils away, as the beaker is kept covered. It is cooled and diluted to about 50 cc. A bent piece of 1-16 in. sheet aluminium about 1 in. square is placed in the solution and boiled briskly till all the copper is precipitated.

The above proportion of water to acid should be adhered to pretty closely, as a more dilute solution takes much longer to precipitate. Samples having much iron and little copper also take longer. The time varies from 5 to 10 minutes.

The aluminium is removed from the solution and washed; the copper does not adhere to it seriously unless the piece of aluminium has become pitted by being used a number of times. The solution is then given a vigorous rotary motion with a stirring rod, causing all the copper to settle in the middle of the beaker. The solution is decanted off as much as possible, more water is added, stirred round, and decanted as before. Two or three such decantations are sufficient to separate all the iron, etc., from the copper, which is dissolved in 5 cc. HNO_3, boiled, diluted, made alkaline with 15 cc. of ammonia, and titrated with KCN solution in the usual way.

The standard solution is such that 1 cc.=0.005 grm. of copper, or 1 cc.=1% when ½ grm. of sample is taken. It requires of 55.60 grm. KCN per litre according to the purity of the KCN used, and depending also on the operator, as two men will not as a rule agree as to the standard.

This is probably the most rapid and convenient method having any pretensions to accuracy. The author hos, however, frequently checked the work of careful assistants who were using this method, against the electrolytic method, and found that the results were very uniformly about 0.2% low.

Determination of Silica.—0.5 grm. of ore is heated in a covered casserole with 10 cc. of HNO_3 until action ceases. (The addition of a few crystals of $KClO_3$ greatly facilitates the solution of most sulphide ores.) It is then uncovered and taken to dryness on an evaporating ring. It is taken up by boiling with 10 cc. of HCl for a few minutes and diluting with hot water.

It is filtered over a vacuum pump, the filtrate reserved for iron and lime determination, and the residue ignited in its filter paper and weighed as "insoluble." This determination will in most cases be the only "silica" required for the smelter routine work.

There will always, however, be some ores on which a determination of true silica will be required. Such a determination necessarily occupies considerably more time. It is effected as follows:—

The insoluble residue is mixed in a platinum crucible with about 2 grm. of sodium carbonate and fused until all action ceases, preferably over a Dangler or other blast lamp.

The following procedure greatly facilitates the subsequent solution:—

Two pairs of platinum-tipped tongs are taken, one in each hand, and the contents are poured from the crucible on its lid. Both crucible and lid are then placed in a cesserole which contains about 40 cc. of cold water. The bulk of the melt which is on the lid really slides off, while the crucible only contains a thin film which is quickly dissolved out.

The casserole is placed in a hot place until all is dissolved or thoroughly disintegrated, when the platinum is removed and the solution acidified with an excess of HCl. The casserole is placed on an evaporating ring and taken to complete dryness, and silica determined exactly as described for silica determination in slag.

The only substance likely to contaminate the silica obtained as above, is barium sulphate. If present in the ore the aqueous solution of the melt should be filtered before adding HCl, great care being taken to ensure that all the silica is in solution. The filtrate is then acidified and evaporated for silica in the usual way.

Barium remains on the filter as carbonate and can be dissolved in HCl and determined as sulphate in the usual way. This will also apply to the silica determination in slag.

Determination of Alumina.—For the purposes of the copper smelter the difference between the "insoluble" and true silica may generally be taken as alumina, and in any case it is only the alumina in the insoluble portion that need be determined, as soluble alumina is not known to exert any harmful influence on copper slag.

When a determination is desired, the filtrate from the true silica, which contains the alumina in a hydrochloric acid solution, is treated for alumina by the phosphate method exactly as has been already described.

Determination of Iron and Lime.—These are determined in the filtrate from "insoluble," as follows: The iron is precipitated with ammonia in the usual way and filtered. The precipitate is washed from the filter through a hole made in the bottom with a pointed glass rod. Hydrochloric acid is poured on, and all the iron washed through with hot water.

The solution is heated, reduced with tin chloride, and iron determined exactly as described for slags.

To determine the lime an excess of ammonium oxalate is added to the ammoniacal filtrate from the iron. It is boiled for a few minutes, filtered, and the calcium oxalate precipitate dissolved and titrated as in slags.

Determination of Zinc.—The determination of zinc in ores is precisely the same as in slags, except that the treatment for the separation of silica is not required. Many ores can be treated directly with the chlorate mixture, but, as its action is very violent on some sulphide ores, it is best to warm gently in a covered casserole with about 10 cc. of nitric acid until the first violent action ceases, then to add from time to time a few crystals of chlorate of potash.

If globules of sulphur separate out, a few crystals or a little powdered $KClO_3$ thrown on top of the globules will cause them to go into solution at once. When all action has ceased the casserole is uncovered, taken to complete dryness, and proceeded with as before described.

Determination of Sulphur.—The solution of 0.5 grm. of ore is best effected in exactly the same way as described above in the determination of zinc in ores, great care being of course taken to see that no globules of sulphur remain undissolved. It is taken to dryness, boiled with HCl, and treated for sulphur as described under slags.

Analysis of Matte.—Though anything like a complete analysis of matte is but seldom required, a great number of copper determinations must be made daily in every smelter.

For iron, zinc and sulphur, matte may be treated exactly as has been already described for ores.

Matte is sampled by dipping a small iron ladle into the stream as it runs from the settler to the conveyor, and allowing the cake of matte to cool in the ladle. Two series of samples are usually taken. One series consists of samples taken every hour, which are collected together and made into a composite sample to represent the average matte produced during each 12 hours. These must be determined for copper by some reasonably accurate method, as the results are required for record in the daily reports, and for calculating the production of copper. Besides this, a series of special samples are taken about every two hours, and more frequently whenever required. The results of these spcial samples are used in the actual control of the furnaces, and must be produced with the greatest possible expedition.

It will be necessary to use, at least, two different methods for this routine work, apart from the most exact method obtainable, which will have to be used on shipping lots if matte is shipped from the smelter and sold as such. These latter are, perhaps, always done either by the iodide or electrolytic methods. These methods have been recently described by Mr. Lowe in his "Technical Methods of Ore Analyses," and fall outside the scope of the present paper.

The average day and night samples may be done by precipitation on aluminium, followed by cyanide titration as has previously been described, while, for the special samples, the most simple and rapid form of the cyanide method is usually employed, the matte being simply dissolved in nitric acid, and the iron separated by precipitation with ammonia. This method has two serious sources of error, some copper being invariably carried down with the iron, producing low results, while zinc, if present, as is most frequently the case, interferes with the method to produce high results.

Both these sources of error can, however, be counteracted, or, at least, minimized by standardizing the cyanide solution with a matte of similar grade and known copper contents.

The following procedure was employed by the author at the United States Smelting Co.'s plant at Kennett, California, and gave excellent results, though the zinc contents of the ore, and, consequently, of the matte, varied very considerably from time to time.

The calculation may seem to be a little complicated at first, but when made with the aid of a slide rule it gives practically no trouble at all, and is fully justified by the results obtained. The details of the method are as follows:—

0.5 grm. of matte is placed in a 10-oz. beaker, and boiled with 10 cc. nitric acid until action has ceased and the red fumes are driven off (matte, by the way, never completely dissolves in HNO_3, a black residue of magnetic oxide of iron being left which, however, is free from copper). 50 cc. of hot water and 20 cc. of ammonia are now added, and the solution brought to a decided boil and filtered through a 15-cm. filter on a fluted funnel into a 30-oz. flask, which is cooled by standing in running water, and titrated when cold with the standard KCN solution.

The average matte samples for the previous day and night are thus run every morning together with all the special samples taken through the night. At the same time the average samples (two for each furnace) are also weighed out into casseroles and determined by the more accurate method.

The subjoined table, arranged for one furnace, will show how the corrected results and the daily standard for the cyanide solution are obtained:

	Rapid Method cc. required.	Approx. Cu.	Al. Method. Cu.	Corrected Results
1. Average day	20.2	20.4	20.6	..
2. Average night ...	16.8	17.0	16.0	..
3. 6 p.m.	16.5	16.7	..	15.7
4. 8 p.m.	16.4	16.6	..	15.6
5. 10 p.m.	16.3	16.5	..	15.5
6. 12 p.m.	17.2	17.4	..	16.4
7. 2 a.m.	17.4	17.6	..	16.6
8. 4 a.m.	16.7	16.9	..	15.9
9. 6 p.m.	16.6	16.8	..	15.8

We will suppose that the standard as determined the day before was 1 cc.=1.01% Cu. The number of cc. in the first column multiplied by this factor gives the approximate results as in the second column. These results can be available early in the morning to show what has happened in the furnace during the night.

The third column shows the true percentage as determined by the aluminium separation for the day and night average samples, from which the new standard is obtained by dividing the true percentage by the corresponding number of cc. in the first column.

A change in the zinc contents has obviously taken place since the previous day, so the new standard is taken from the average night sample thus—

$\frac{16.0}{16.8}$=0.952. This factor is then taken to be used for the day for the special samples. The fourth column shows the special night samples corrected by its means.

The method cannot be expected to give very accurate results in case of a sudden change of zinc contents, but it is always possible to obtain a new standard by redetermining one of the special samples of the aluminium method.

MEETING OF THE TORONTO BRANCH OF THE CANADIAN MINING INSTITUTE

It is seldom that a more thoroughly representative body of mining men has been gathered for a meeting of the Toronto Branch of the Canadian Mining Institute than when, on the evening of November 19th, the Toronto members attended an informal dinner at the St. Charles Restaurant.

The guest of the evening was Mr. H. E. T. Haultain, whose appointment to the position of Professor of Mining and Metallurgy at the University of Toronto has been fully noted in these columns.

Before 7 o'clock the dinner was in full swing. In addition to the Toronto members there were present representatives from Montreal, Cobalt, and other branches.

When the dinner had been disposed of, the chairman, Mr. Eugene Coste, in a brief speech, alluded to the fact that the dinner had been arranged in honor of Professor Haultain. He then called upon Mr. G. R. Mickle, Provincial Assessor of Mines.

Mr. Mickle, as the former occupant of the chair of mining, tendered his congratulations to his successor. He was satisfied that Mr. Haultain would fill the position with honor to the University and to himself. He and Mr. Haultain had been students together. He had every reason to believe that Mr. Haultain could understand and sympathize with the vagaries and idiosyncrasies of his own students. Mr. Mickle concluded with a warm tribute to the vigor and ability of his successor.

Mr. J. B. Tyrrell was next called upon. After dwelling upon the need of radically modern methods of instruction in equipping mining students for present day work, Mr. Tyrrell assured Mr. Haultain of the support and sympathy of the mining fraternity under

all circumstances. "The appointment is one," said Mr. Tyrrell, "that merits and receives the fullest approbation of mining men."

The chairman next called upon Dr. W. G. Miller, who, in a most felicitous manner, dwelt upon the good fortune of the University in securing Mr. Haultain, and the equally good fortune of the Ontario Bureau of Mines in acquiring the services of Mr. Mickle.

Mr. Alex. Gray, of Montreal, spoke in terms of high appreciation of Mr. Haultain's appointment. He found it hard to determine whether the step meant more of gain to the University than of loss to the practical mining world. He desired, in conclusion, to touch upon a matter of national importance, a matter upon which clean mining men were of one mind. The present Cobalt boom had produced a distressing crop of wildcats. A few months ago the proportion of dividend-bearing shares sold and handled in Toronto and Montreal was about 86 per cent. of the whole. Now, however, the percentage had fallen to less than 34. This was an eloquent fact. Only the dissemination of mining knowledge and the hearty co-operation of decent technical men with the technical journals could remedy this. And a cure could not be effected in a month or a year; it must be a gradual and thorough process.

The guest of the evening was then called upon by the chairman. Mr. Haultain expressed his sense of gratitude for the honor that had been shown him as the incumbent of a most important office. When he had been a student at Toronto University no instruction in mining was provided. Now the whole scene was changed. The Department of Applied Science now takes care of about eight hundred students. The number of those studying mining branches in about one hundred. He had been surprised and gratified at finding such sound provision made in all the branches. The University had never advertised. The public knew little of what was being done. The members of the faculty had been kept busy providing for the phenomenal growth of the University. He wished to emphasize particularly the careful, quiet, but admirably farsighted work done by his predecessor, Mr. Mickle. Mr. Mickle had made no display; he had resisted all temptation to indulge in trimmings and frills. But he had laid the best and soundest foundation upon which his successor could work. The University generally and the Departments of Applied Science in particular were throbbing with the spirit of growth because of just such unselfish labors as those of Mr. Mickle.

Mr. Haultain continued his convincing and incisive speech with an urgent appeal to the mining men present to come and see what was being done and to take a more vital interest in the mining students, whose ideals and convictions they could do much to mould and crystallize. He then touched upon the criminal lengths to which promoters of nefarious mining schemes were allowed to go. He strongly commended the attitude taken by Mr. Gray, and deplored the indifference of many who could assist in eradicating the evils that are now so prevalent.

During the regular meeting that followed the dinner the following resolution was unanimously passed, and the Secretary of the Toronto Branch was instructed to forward a signed copy to Sir Wilfrid Laurier:—

A Resolution Passed at a Meeting of the Toronto Branch of the Canadian Mining Institute, Held in Toronto, on Nov. 19th, 1908, With Instructions That a Copy be Forwarded to the Right Hon. Sir Wilfrid Laurier, Prime Minister of Canada.

Resolved, That the Toronto Branch of the Canadian Mining Institute desires to testify to the sympathetic and constructive interest shown by the Hon. Wm. Templeman as Minister of Mines, and respectfully expresses the hope that in the interests of the mining industry the services of the Hon. Mr. Templeman be continued. The unanimous opinion of this branch is that a break in the continuity of the Hon. Mr. Templeman's work would be most regrettable. We desire, therefore, to express the hope that you will adopt such measures as may seem best to you to retain the Hon. Mr. Templemon in charge of the Department of Mines.

EUGENE COSTE, Chairman,
J. C. MURRAY, Secretary.

The following resolution also was presented and passed without a dissenting voice:—

Resolved, That in the opinion of this meeting, the promotion of fraudulent mining schemes, abetted by newspapers, is being indulged in to such an extent that the legitimate development of the mining industry is being very seriously injured, and, further, that this meeting learns with a great deal of pleasure that the Provincial Secretary has determined to see that henceforth all advertisements conform strictly with the provisions of the Ontario Companies Act. In the opinion of this meeting such a step will do much to curtail the operations of fraudulent speculators.

ALUMINIUM AND SOME OF ITS USES

By J. T. W. Echevarri, M.I.Mech.E.

(Paper read before the Institute of Metals, First Meeting, Birmingham, Eng.

Aluminium, although discovered as far back as 1827 by the German chemist, Woehler, was not used to any extent till the electrolytic method of extraction, invented simultaneously by Heroult in Europe and Hall in America, enabled it to be produced on a commercial scale and at a price comparable with the other common metals. Since then improved methods of manufacture have enabled the price to be still further reduced, till to-day aluminium is, bulk for bulk one of the cheapest of the common metals. The following table shows the steady fall in pric eduring the last twenty years:—

Price of Aluminium per ton.

	£
1889	3,256
1891	812
1892	495
1896	163
1901	130
1905	130-170
1907	200-160
1908	100-65

On its first appearance the new metal was hailed as a panacea for all the ills the metallurgist is heir to, and its use was proposed for every imaginable purpose, from armour plate to chemical chambers, and it was

this very exaggerated idea of its scope of usefulness which in the end militated against its employment for those purposes for which it is most suited, for its failure to stand up under obviously unsuitable conditions led to a general distrust in the new metal, which it has taken years to live down.

The enormous demand and consequent high price of aluminium during the copper boom of 1906-1907 also seriously affected its development; as many of those who would have been glad to use the metal were forced by its rising price to give up their projects or to turn their activities in other directions. This large demand, however, induced the manufacturers to lay down increased plant to turn out the metal in large quantities, the benefit of which we are to-day reaping in the very low price at which the metal now stands.

Manufacture.

Aluminium is now obtained electrolytically from bauxite, a clay containing a high percentage of aluminium oxide, cryolite being used as a flux. The chief improvements that have been effected since this method was first employed lie in the exclusion of the impurities contained in the raw material, for whereas formerly commercial aluminium rarely contained more than 98 per cent. of aluminium, most of that turned out by the British Aluminium Company, Limited, to-day carries close upon 99½ per cent. of aluminium, whilst metal with as little as 0.4 to 0.3 per cent. of impurities is obtainable for special purposes. For ordinary requirements, however, such high degree of purity is unnecessary, and does not repay the extra cost of manufacture.

Imprities.

The impurities commonly met with in aluminium are iron, silicon, and sodium. Silicon renders aluminium very brittle if present in large quantities, and this drawback does not appear to be offset by any corresponding advantage. Silicon also impairs the resistance to corrosion peculiar to pure aluminium, promoting the decomposition of the metal. In this connection it is interesting to note that the thin yellow coating which forms on the inside of cooking utensils is largely composed of silicon. In high-grade aluminium the percentage of silicon should in no case exceed 0.4 to 0.5 per cent., although the metal as used in iron and steel works may contain double this amount of impurity.

Iron occurs in high-grade aluminium to the extent of about 0.2 to 0.3 per cent., and whilst somewhat impairing the ductility of aluminium in the same way as silicon, the tensile strength is somewhat improved by its presence in small quantities. The presence of iron does not appear to affect the electric conductivity of aluminium to the same extent as silicon, but has a bad influence on its non-corroding properties. Sodium is the most injurious impurity to be found in aluminium, as the resistance to corrosion is seriously lowered by even small quantities of this metal. Improved methods of manufacture have, however, eliminated all but the minutest traces of this elemen,t till to-day more than 0.006 per cent. of sodium is rarely found, half this amount being the more usual figure.

Physical Properties.

The pure aluminium of commerce is a silver white metal, with a melting point of 657 degrees C., and a specific gravity ranging from 2.56 to 2.72, according to its method of treatment. Copper having a specific gravity of about 8.8, zinc about 6.9, and tin about 7.3, it follows that aluminium is about 3.3 times as light as copper, 2.5 times as light as zinc, and 2.7 times as light as tin. The heat conductivity of aluminium is high, being second only to copper among the common metals in this respect. Its electrical conductivity is also high, being from 60 to 62 per cent. of that of pure electrolytic copper; it having, like copper, a somewhat lower resistance when soft than when hard drawn.

Mechanical Properties.

The strength of pure aluminium depends to a large extent on its method of treatment, but the following tables gives average figures for the metal in various forms in tons per square inch:—

	Ultimate tensile strength.	Yield point.	Elongation p. ct.	Modulus of elasticity.
Sand castings	5.0	2.5	25	.....
Chill castings	5.25	2.5	35	.....
Rolled bars	7.0	5	35	.....
Rolled sheet	9.0	8.5	6	.....
Drawn sections	8.75	8.5	20	.....
Hard drawn wire	15.0	13.0	25	9,000,000
Soft drawn wire	7.0	4.0	30	10,000,000

Methods of Working.

Aluminium may be melted in ordinary plumbago crucibles over a coke fire, but where quantities are to be melted a reverberatory coal furnace is generally used. The metal should not be heated above 725 deg. C., to avoid "burning," as at this temperature aluminium readily oxidises with the oxygen in the air. Sheet iron can be re-melted by submerging in the molten metal, the loss being only from 2 to 3 per cent., which is much lower than in the case of brass and similar metals.

Aluminium can be cast in either sand or chill moulds, the latter method being generally employed where a good finish is required on small plain castings. Aluminium cast in polished steel moulds has a finish equal to the best machined surface. For rolling it is cast into large slabs or blocks, which are afterwards broken down hot, the intermediate and finishing stages being done cold, the amount of annealing being governed by the temper and finish required.

Aluminium can be easily drawn into sections, tubes and wires, more or less the same methods being employed as for copper. The billet is first rolled down hot to a convenient size, and afterwards reduced to the correct section on the drawbench, cold fat being used as a lubricant. For drawing down to the finer gauges in the wire-drawing machines, paraffin is employed as a lubricant. The amount of annealing during the process depends upon the temper required. Wires from ¾ in. to 0.018 in. diameter can be drawn in this manner, these being used for practically all purposes where copper, brass or German silver wire is used.

Sections, rods and tubes in aluminium can also be made by forcing the solid metal, at a temperature of about 80 deg. C., by means of hydraulic pressure through suitable dies, this method being economical only where a great number of lengths of the same section are required, owing to the cost of the plant necessary. Soft aluminium sheets can be spun, stamped, or pressed into various shapes, cocoanut oil or other lubricant being used.

For turning, a sharp-edged tool with a good clearance should be used, and the work run at a very high speed combined with a slow traverse, plenty of lubricant in the shape of soap and water or paraffin being

used. For drilling holes a diamond or nose drill with ample clearance should be used, a twist drill being liable to seize. Screw threads can be cut with an ordinary tap, using a little light oil as a lubricant.

Aluminium can be soldered by means of the various special solders now on the market, but as such soldered joints are all more or less subject to electrolytic action in the presence of moisture, they are only suitable when protected from damp air. Welded joints, being entirely of aluminium, do not suffer under these conditions, and this method is being more extensively used now that satisfactory welded joints can be made by means of portable oxy-acetylene blowpipe equipments.

It had long been recognized that this was the most hopeful direction in which to experiment, because such joints, containing as they do nothing but aluminium, would be as free from electrolytic action as the metal itself, but the difficulty met with was in getting rid of the film of oxide, which prevented the two surfaces uniting properly. In the case of the butt welding of small rods and wires, this difficulty can be easily overcome by applying end pressure at the moment of fusion to drive out the film of oxide, but in the case of sheets and plates this method is not practicable, and recourse had to be made to some other method. Lately several fluxes have been put on the market capable of dissolving the film of oxide and permitting the metal to flow together with perfect ease. Another method of welding aluminium sheeting which shows promise of success, and which would repay further investigation, is the electric system of welding, by means of so-called spot welders; this method being extensively used for copper and iron sheet. The electric welders as used for copper and iron wire are also suitable for aluminium wire with certain modifications.

Applications.

Iron and Steel Works.—Aluminium is used in iron and steel works, for removing the oxygen from the oxides of iron, and many other substances, with which it comes in contact, the heat generated by this reaction being so great that it may be also of service in raising the temperature of large bodies of iron.

The efficacy of small quantities of aluminium in preventing "porosity" is also very marked. Porosity is due to the partial disengagement of gases absorbed during melting, which are imprisoned as the metal cools. Aluminium appears to have the property of combining chemically with these gases and producing an innocuous slag.

It frequently arises in small works that a casting requires two "blows" of the cupola. In this case the difficulty of keeping the first tapping hot while the second charge is running down may be readily overcome by adding from time to time small quantities of aluminium to the metal in the ladle. The rise in temperature obtained effectually prevents the metal from excessive cooling.

For the purpose described, the metal may be employed in various forms. An alloy known as ferro-aluminium, consisting of about 90 per cent. of iron and 10 per cent. of aluminium, is used by many iron and steel founders, this material being so brittle that it is a simple matter for the user to break off the right amount to suit his own requirements. The use of ferro-aluminium has, however, been largely superseded by that of the pure metal, which is generally supplied in the form of notched bars and half-round bars, easily cut up into small pieces for use.

Some steelmakers use aluminium in a form known as "granulated." This consists of a powder which may vary in coarseness from that of rice down to that of sifted sugar. Where the heating effect of the burning metal is alone required granulated aluminium may be profitably used, and is generally mixed with sufficient smith-scale to provide the oxygen necessary for its combustion.

The makers also supply iron and steel founders with aluminium in small uniform pieces weighing exactly ⅛ oz. and ¼ oz. each respectively, so that the user is saved all trouble of weighing, and can add any predetermined percentage of aluminium to his iron or steel with a minium of delay and inconvenience.

A further application of this principle has been made in the "Thermit" welding process invented by Dr. Goldschmidt, where the heat of combustion of aluminium and oxygen is made use of to raise the temperature of iron and steel castings, etc., to the welding point.

Aluminium Castings, etc.

Aluminium is used for many purposes in the building of motor cars, where stiffness combined with lightness is desired. Among these may be mentioned crank-cases, gear-boxes, carburettors, radiators, and dash-boards, besides many small details, such as control levers, lubricators, etc., and it is, besides, finding a large and increasing outlet with engineers, brass-founders, and others, for a variety of general castings.

For castings, it is found of advantage to alloy the metal with copper, zinc, or nickel, which increases the strength and makes it easier to work, without materially increasing the weight.

Sheet Aluminium.

When rolled into sheet, the uses of aluminium are too numerous to mention, as the light metal is every day finding its way into new channels in competition with older metals. The reason for this will be easily seen when it is remembered that at to-day's prices a rolled sheet 6 ft. by 3 ft. by 1-16 in. thick, having an area of 18 square feet in—

Aluminium	weighs	16	lbs.	and at	1s.	1d.	per lb.	costs	17s. 4d.
Brass	"	49½	lbs.	"	0s.	6½d.	"	"	26s. 10d.
Copper	"	52	lbs.	"	0s.	7½d.	"	"	33s. 7d.
German silver	"	50	lbs.	"	1s.	2d.	"	"	58s. 4d.
Pure tin	"	42½	lbs.	"	1s.	5d.	"	"	59s. 10d.

Other thicknesses of sheets, tubes, rods, beadings, mouldings, angles, channels and other sections will, of course, be in similar proportion.

In the early days of aluminium, sheets composed of copper alloys were used to some extent in connection with shipbuilding. It has, however, since been demonstrated that for all such work only pure aluminium of the best quality should be used, and there is little doubt that naval constructors will find pure aluminium sheets, channels, mouldings, rivets, etc., of great assistance in partitions, ceilings, deck and chart houses, and similar portions of large ships, above the water line, where reduction of top weight is of importance in connection with the stability of the vessel. In 1901 a quantity of large aluminium plates was used in the chart house of the steamship Celtic, and the owners report that the condition of the material is satisfactory.

Aluminium Tubes.

Large quantities of specially pure aluminium tubes are being used for various purposes in connection with acid work, under which condition the pure metal re-

mains practically unaffected. In order to demonstrate the usefulness of aluminium tubes for steam coils, etc., some tests were made at Milton Works some time ago with the following results:—

Length of tube. in.	Gauge.	O/s diameter in.	Tested to lbs. per sq. in.	Remarks.
12	10	3¼	1,200	Expanded to 1-32 in. in middle but returned to original size on release of pressure.
12	12	2 11-16	1,200	Ditto (barely 1-32 in.).
12	14	2	1,200	As above, with rather less expansion.
12	14	1⅛	1,200	Perfect. Would probably stand considerably more.
12	19	1⅛	1,200	Ditto.

All the above were afterwards tested at 100 lbs. per square inch for half an hour, with the exception of the second on the list, which was under the steam test for 12 hours without apparent injury. This tube was, after the steam test, subjected to a second test of 1,200 lbs. hydraulic pressure without showing any signs whatever of fracture.

Electrical Industry.

As a conductor of electric current aluminium has a large and increasing field of usefulness, the difficulties at first met with in regard to jointing, etc., having now been overcome. The saving that can be effected by using aluminium in place of copper for overhead conductors is so large that in countries where long overhead transmission lines are in vogue the lighter metal practically reigns supreme. In this country there has not been up to the present the same opportunities for long distance bar overhead transmission lines, but during the past few years there have been erected many short distance aluminium lines for lighting and power requirements in connection with works, collieries, etc. With the increasing use of electricity for motive power purposes, aluminium conductors are being adopted much more extensively in such directions, engineers and consumers alike appreciating the immense saving in capital outlay secured thereby. Further, at the present low price of aluminium, the saving in cost of the bare conductor is so large that there is an extensive field for the metal for insulated underground cables, even taking into account the increased amount of insulation necessary for the somewhat larger cable.

Aluminium as used for electrical purposes has a conductivity equal to about 61 per cent. of that of pure electrolytic copper, so that to obtain the same conductivity it is necessary to increase the sectional area by 64 per cent. above that of copper, corresponding to an increase in diameter of 28 per cent. for a round conductor. Copper being 3.3 times heavier than aluminium, we see that the somewhat larger aluminium conductor will still weigh less than half of the equivalent copper conductor, the larger cooling surface of the aluminium conductor being a further factor in its favor.

For bus-bars and back connections in switchboards aluminium is also finding an increasing use, the saving in weight allowing of lighter supports and framework, which means additional economy over and above the saving in cost of the conductor. For the front of switchboards, aluminium is also eminently suitable for such fittings as bolts, lamp-holders, instrument cases, etc., the effect against a dark marble board being very pleasing.

There are several satisfactory methods of jointing aluminium conductors, according to the conditions under which it is called upon to work.

For small diameter wires as used for making up into cable the usual butt welded joint is made either in the flame of a blowpipe or by means of the electric welders as used for copper.

For bare stranded cables the usual method is to weld the two ends together by pouring molten aluminium into a cigar-shaped mould, previously clamped around the joint, but where high tensile strength is required a mechanical joint may be used, so designed as to give a wedging action when pulling tight in order to ensure good electrical contact.

For insulated underground cables it is not always practicable, to use welded joints on account of the confined space when working in closed boxes, and in this case either a mechanical or a soldered joint may be used, where the joint is afterwards protected from atmospheric influence. The simplest method is to slip a tube over the two ends of the cable with a slot through which the solder can run. The resistance of such joints is somewhat higher than in the case of welded joints, but they compare very favorably with copper joints made on the same principle.

The tensile strength of hard drawn aluminium wire is equal to about half that of a copper wire of equal section, but allowing for the increased size of an aluminium conductor to obtain the same conductivity as for copper, this figure is raised to about 75 per cent., the difference being more than compensated for by the decreased weight of the aluminium cable.

Alloys of Aluminium.

The alloys of aluminium in common use are confined almost exclusively to combinations of the metal with zinc, copper, and nickel. In general, the proportions of these metals which can with advantage be added to the light metal, do not largely exceed 20 per cent. in the case of zinc, 6 per cent. in the case of copper, and 5 per cent. in the case of nickel. A very interesting and valuable—especially for marine work—series of alloys, known under the name of aluminium bronzes, is also produced by the addition of aluminium in quantities up to 10 per cent. to electrolytic copper.

Salt is purified by melting in the new and rapid English process. The crude rock-salt is fed automatically to a table contained in a large furnace, is then fused, and runs into troughs, from which it is drawn at one side of the furnace into large caldrons. Air is forced into the molten mass, and lime is added. The impurities sink to the bottom, and the upper portion is ground and screened, while the lower part is used for chemical manure.

In the novel tool-tempering apparatus of W. Rosenhain, as exhibited at a soiree of the London Royal Society, the metal is heated in a vacuum tube, and at the required temperature shown by a thermo-electric indicator—is quenched by admitting water. The new silica tubes admit of sudden cooling from redness or greater heat.

Lead-wool consists of pure lead cut into fine strips by machinery, and is put up in pound skeins of yard-long threads. For making tight joints it is simply laid in the joint socket and pounded in with a caulking tool. It welds into a solid mass, filling every interstice, and it ensures more thorough work than results from using molten lead.

COBALT COMMENTS

By Alex. Grey

Nova Scotia Co. Prospects.—Statements contained in the annual reports of the consulting engineer and the secretary-treasurer of the Nova Scotia Silver-Cobalt Mining Co. offer commingled consolation and qualified promises of dividends, of which shareholders were beginning to wonder if l'appetit vient en mangeant. The company concerned is exceptional in that its mining area is in the Keewatin. It is capitalized at $2,000,000, all issued, and valued in the market at about $1,200,000. The character of the directorate and technical control is a guarantee that what there is will out, and it is urged that they are doing their utmost under stress to "make a satisfactory showing in the shape of dividends to the shareholders." As they are among the most representative mining capitalists engaged in the Northern Ontario fields, with many "irons in the fire," as they have not been identified with hurdle-racing markets, there is a measure of justification for the complaint registered by Mr. Benjamin B. Lawrence that "many stockholders fail to appreciate that it is impossible to do two things at the same time, namely, open up a property as this has been opened up, and make substantial earnings while you are doing it."

The mine that pays for its own development is the exception. Cobalt's mines have done it in greater degree than those of any other camp, because their virtues were naturally necessitous. They had to provide their own working capital, pay brokerage charges, meet vendor considerations. Owing to the Nova Scotia being so well groomed those who fancied the stable's choice should not be impatient; yet the situation seems to call for exchange of views rather than censure on either hand. The issued capital constitutes a liability to meet which reliance is placed in owned and leased ground adjoining and under Peterson Lake. Elsewhere 1,100 feet of driving and 500 feet of cross-cutting in the Keewatin "were unsuccessful in finding any regular or permanent ore chute. Some very rich ore was mined in various portions of the property, but the occurrence was mostly in small pockets, which although rich in silver, failed to yield any substantial quantity."

So writes Mr. Lawrence and nothing could be more to the point. A cross-cut disclosed what is particularized as "the pay chute" and as the Nova Scotia had only 40 feet of it, thirty acres were leased for 10 years from the Peterson Lake Company. The vein has since been followed for 200 feet; there is about 50 feet of "backs," and the values occur "as native silver scattered through the vein filling for a width varying from 5 to 10 feet." A winze proved the ore body to a further depth of 25 feet "in the Peterson Lake ground," and it is the opinion of Mr. Lawrence that "within 60 days we should have sufficient ore exposed to warrant our producing ore in quantity, say from 30 to 40 tons a day, which should yield a handsome return."

So far as these representations go, they reflect the thoroughness with which explorations have been prosecuted. They are insufficient for the speculative position, and those who grumble at this have only themselves to blame. Capital liabilities as against ore disclosed is somewhat Cobaltesque, but the $75,000 spent upon plant, the "two working shafts and some 1,900 feet of development in drifting, cross-cutting, sinking and raising," and the lease of adjoining territory known to contain the extension of "the pay chute," must suffice for speculative coteries who rarely take into account the idiosyncracies of "the vein calcite." However, during the twelvemonth ending August 31, 149 tons averaged $765.10 per ton or $114,000 in the gross. In August, 28 tons shipped averaging $603.57, or $16,900 in the gross, permitted a profit of $8,000 after paying working costs of $8,978. This is at the rate of 4.80 per cent on capital and if tonnage to be developed broadens this dividend aspect, there is the added assurance from Mr. Lawrence that "concentration" of the ores "inasmuch as the values are scattered through substantial widths, requiring the handling of a heavy tonnage," will be superseded by a process capable of "a large tonnage." Mr. Lawrence is "happy to say that it now looks as if" the separation "problem would be solved" to the "entire satisfaction" of shareholders. Taken in connection with the statement of Mr. Jacobs that the Nova Scotia management "will undoubtedly handle a very much larger quantity of material than is generally the case of Cobalt," the practical process evolved by Mr. Lawrence will be a welcome demonstration. It and the developments of another year should prove the perseverance or otherwise of the Nova Scotia ore bodies. If the section is inadequate the directorate are strong enough to find something that will be all-sufficient to obviate permanent disappointment. Meanwhile there is difficulty in subscribing to the pronouncement in the Unted States Investor of October 1 that "it is estimated by well-posted mining men that upwards of $1,000,000 worth of good ore is blocked out."

McNicol and Pickens, miners of Butte, established a world's record for rock drilling by driving a hole 56 5-8 inches, 7-8 inch bits, into a solid block of granite in 15 minutes at the Spokane Interstate Fair competition. The performance, which was witnessed by 20,000 men, women and children, netted them $750. McNicol weighs 215 pounds, while his partner is 15 pounds lighter. They used 20-pound sledges. One of the features of their work was the dexterity displayed in changing drills, this being done without missing a single stroke. The best previous record was 55 inches, drilled by Bradley and Frathey, of Spokane, five years ago. Other teams in the contest this year were: McGilvray and Erickson, of Silverton, B.C., 52 7-8 inches; Naylor and Anderson, of Burke, Idaho, 43 3-4 inches, and Johnston and Dunn, of Silverton, B.C., 43 1-8 inches.

For slow-speed pumps in the Rand mines, South Africa, a novel fly-wheel has been adopted. High freight rates make iron and steel machinery very costly, and the use of concrete rims for the fly-wheels of ten pumps is stated to have realized a saving of about $10,000. The fly-wheels are driven by electric motors through worm gear about 20 revolutions per minute. Each wheel is 14 feet in diameter, with cast iron bosses in which sixteen spokes of four-inch tube are screwed, and the rim has a base and an outside of ¼-inch sheet iron strips, separated by distance pieces. The strips are bolted together, the concrete rim between being 13 inches wide and 13 inches deep, strengthened by four ¼-inch wires interlaced with the distance pieces. The weight of the wheel is 8,000 pounds, and that of the rim 6,000 pounds.

CORRESPONDENCE.

Editor Canadian Mining Journal, Toronto:

Dear Sir,—I have read with a great deal of interest the paper by Mr. O. N. Skelton on "The Taxation of the Mineral Resources in Canada." I have probably had a better opportunity tha nanyone else of studying this matter during the last year, but do not consider it proper for me to enter on a discussion of any of the principles or subjects which are contentious, and I shall therefore merely qualify some of the statements made about the working of the Act taxing the mineral resources in Ontario, which are misleading without some explanation. In the first place, the results for the year 1907 (the year the Act came in force) are obscured by the fact that there was at first no limitation of the amount which might be deducted from the provincial tax by the municipalities for income tax, the Act having been amended in that respect since. There is no definite basis in the Municipal Assessment Act for determining what the income of a mine is, whereas the mode of computing the provincial tax is very specific and clear. Moreover, the municipalities claimed the right to assess the estimated income for the current year, whereas the provincial tax is based on results of the preceding year. It was therefore inevitable that the two assessments should clash and make the results very erratic.

The amount given as collected under the Supplementary Revenue Act is taken from the Provincial Treasurer's statement, which was for the calendar year of 1907. As the tax was not due until the first of December, 1907, a great deal of it—fully one-half, in fact—was not paid until 1908, and does not appear in the statement at all. In the same way the statement for 1908 will be too large, as it will include these taxes for 1908, which will probably be paid in before the end of the year, the tax now being payable on October 1st. A statement which is complete, except so far as acreage tax is concerned, will appear in the Report of the Bureau of Mines. It is impossible even at the present time to say what the actual amount of the acreage tax paid for the year 1907 will be, as payments are coming in almost daily for 1907 and 1908.

Further on the statement is made that 300,000 acres were forfeited in Ontario for non-payment of the tax of one cent per acre in the year 1906. As a matter of fact the time limit when forfeiture can take place under the old one cent tax has not yet arrived, and there is still over a year to run before anything can be forfeited under the two cent tax. The slaughter will probably be immense when the time limit for the present two cent tax expires and forfeiture takes place. The 300,000 acres referred to were cancelld for non-payment of rentals, which is, of course, an entirely different thing.

The suggestion that acreage taxes should be grauated, being low for the first few years after acquisition and changing from year to year, appears to me most impracticable, judging from my experience of the difficulty of distributing the information among the thousands of holders of mining lands that a tax of two cents per acre was due. A tax changing from year to year would entail endless work and consequently a great deal of expense, and would only exasperate the owners of mining lands. It must be borne in mind that the amounts are usually small, and the holders scattered far and wide, and therefore whatever tax is levied should be as simple as possible, and should not be constantly changed.

The tax on natural gas is considered in the paper as virtually an export tax. It is a great deal more than that, as it has proved a most efficient means of preventing the waste of natural gas by operators who are indifferent about gas, but are seeking oil. This waste destroyed incredible quanties of gas in the old Essex field, and contributed probably mainly to its rapid depletion, and was going on at an alarming rate in other fields in Ontario when the Act came in force.

Yours truly,

G. R. MICKLE.

Toronto, November 16th, 1908.

Editor of the Canadian Mining Journal:

Sir,—I enjoyed your Calgary effusion very much. Some one, though, gave you the wrong "steer" about it. The fact is, that I am the only one who knows exactly what transpired; fear deprived the others of their powers of observation, i.e., our secretary in his description talks about the "steers being led out of the corral." I have modestly but peremptorily "to resign that proud eminence" as the hero of the occasion—in favor of our worthy President. I was standing near him when the steer charged. Did he, panic-stricken, impale himself on the barbs of a wire fence or climb a post? His hungry eyes—as did forty other pairs—swept the far-flung vista, but no St. Charles oak spread forth its beneficent branches anywhere over that treeless plain. Whether, like the British man-of-war in the harbor of Apia, Samoa, which headed for the open sea when the other battleships, vainly attempting to anchor, were dashed to pieces on the rocks, he preferred the open plain, eagerly longing to pit his agility against the steer's; or whether, that acuteness of observation in the field which is at once the envy and despair of his geological colleagues, enabled him to espy the telegraph pole, will probably never be known. Suffice it, he hurled himself across the intervening space like a mountain torrent in the spring or Frank Law after a servant girl's savings. Did he look behind him? He disdained to, and besides there was no time for it. The goal was reached, the race was won, and all records broken. The time for the hundred dash is only an official record in sporting circles. We of the Institute can boast of having a President who has covered the hundred yards faster than any man the world has ever seen.

In regard to our Secretary, his grey molecules were gyrating at such a terrific rate that he thought the steers were being led out of the corral on a string.

Yours for truth,

THE MAN FROM COBALT.

Cobalt Ont., Nov. 13, 1908.

The Pulsometer Engineering Company, Ltd., Reading, England, were awarded a gold medal by the International Jury of the Franco-British Exhibition. The medal was awarded for their exhibit of a new patent Desicating and steam air pump, the invention of Mr. H. A. Fleuss, who is also the inventor of the celebrated "Geryk" vacuum pump, to which a silver medal was awarded at the St. Louis Exposition in 1904.

BOOK REVIEW

A Manual of Underground Surveying.. By Loyal Wingate Trumbull, M.E. Illustrated. 251 pages. $3 postpaid.. The Hill Publishing Company, 505 Pearl Street, New York, 1908..

The practice of mine surveying, like assaying, has in America developed characteristics that distinguish it from British and European practice. Mr. Bennet Brough's text-book, excellent as it is acknowledged to be, is more especially adapted to the requirements of mining engineers in Great Britain than in this country.

Mr. Trumbull's volume is the first attempt to embody in one volume the best features of American mine surveying. It is a careful compilation of material selected from magazines, technical publications, and catalogues. To this material are added descriptions of methods actually in use in many important mines. These have been contributed at Mr. Trumbull's request, and it has been his object to select only the most approved methods.

A knowledge of plane surveying is presupposed. Neither the theory nor the methods of ordinary surveying are touched upon.

Copious bibliographical notes are appended to several of the chapters. These should prove most instructive.

Chapter I., on instruments, includes a readable dissertation on the history of the transit. The chapter comprises 63 pages, and is clear and well illustrated.

Then follow chapters on "Meridian," "Underground Practice," "Carrying the Meridian Underground," "Survey of Secondary Openings," "Record of Survey," "Uses of the Mine Maps," "Making the Map," "Map Filing," "Bore-Hole Surveys," "Methods of Various Engineers." The last chapter gives the United States Deputy Mineral Surveyor's examination. A good index completes the volume.

In glancing through this manual, we have been impressed with the practical tone that pervades each chapter. It is pleasant to notice that such subjects as sampling, assay-maps, bore-hole surveys, waterproofing maps and blue-prints, are not neglected. Indeed the book is thoroughly modern, practical, and well-arranged. The most critical can ask for no more than this.

The Journal of the Canadian Mining Institute, 1908. Edited by the Secretary. Volume XI. 616 pages. Illustrated. Published by authority of the Council at the Secretary's Office, 413 Dorchester Street W., Montreal, August, 1908.

As an annual record of the work and growth of the Canadian Mining Institute, and as a permanent source of reference on many mining and metallurgical subjects this volume is considerably more significant than its predecessors.

In all there are forty-one papers, which may be grouped roughly into those dealing with the geology and metallurgy of Canadian iron ores; those dealing with fuels; one on graphite; one on gold; six describing the geology, mining, concentrating, and metallurgy of Cobalt silver ores; seven touching on the ores and mines of British Columbia. In addition there are nine papers on miscellaneous subjects, and four excellent descriptive papers contributed by students.

The general index, compiled by Mr. F. Nicolas, of Ottawa, is the work of a finished index-maker.

It will be seen that the range of subjects covered is wide. Not only is this the case, but nearly every paper is of a high degree of excellence.

The editor, Mr. H. Mortimer Lamb, is to be felicitated upon the contents and appearance of Volume XI. Clear type, good paper, excellent half-tones and diagrams, along with careful editing, are features to be commended.

China-Clay: Its Nature and Origin.

In the Transactions of the Manchester Geological and Mining Society, Vol. XXX., Part XX., there appears an exhaustive article on the nature and origin of china-clay, by Mr. George Heckling, B.Sc.

"Kaolin," or china-clay, is prepared by directing on to the "rock" (decomposed granite) in the quarry a head of water, which sweeps the material away to a series of catch-pits. In these pools the suspended material settles, the coarsest particles in the first, the finer material in the next, until the last poor gets only the finest mud. This last, when dried, is the best china-clay, and appears to the eye perfectly homogeneous. But both coarse and fine materials are composed of varying proportions of quartz, mica, kaolinite, and tourmaline. In the coarse settlings quartz greatly predominates, while tourmaline, biotite, and white mica make up the remaining material. In the finer material quartz and tourmaline diminish, while mica increases and soon preponderates. In the very finest claps, kaolinite and white mica make up 90 per cent. of the total, and quartz almost the whole of the remaining 10 per cent., tourmaline forming 1 per cent. or less. This composition is usual in good clays.

China-clay-rock is the result of the complete weathering of igneous masses in situ. Most common sediments are probably the result of less complete weathering, in which the material is removed so soon as decomposition has proceeded far enough to set it loose.

Asbestos wood, which seems to be attracting attention as a new structural material, is made chiefly from asbestos fiber, and is about two-thirds as strong as ordinary wood and takes a higher polish. It is as easily worked as oak and maple, while nails hold in it better. The material is now usually made in sheets three by four feet in size, and is adapted for roofing and walls, but it can be panelled for wainscoting or doors, or moulded into ornamental trimmings.

A novel device for measuring the hardness of metals is called the scleroscope by Albert F. Shore and Dr. Paul Herould, its inventors. A steel ball weighing 40 grains, made extremely hard by a special process, is enclosed in a glass tube, and the hardness is indicated by the reboudn as the ball is dropped on the metal under test. A scale measures the height of rebound. On this scale 100 is the average hardness for carbon steel, and proves to be the safety limit for steel tools after reheating and tempering. The instrument is valuable in making tools of standard hardness.

EXCHANGES.

The Engineering and Mining Journal, November 14, 1908.—Mr. John A. Church, writing on "The Principles of Machine Sampling," predicts a largely extended use of sampling machines in the close future. "At present," says Mr. Church, "the work done is so irregular that I feel it is high time the whole engineering profession should . . . determine what can be done to improve the work." The closely guarded results of tests from one establishment cannot do anything like the good that will be derived from a series of comparative resamplings from every mill in the country.

On copper ores containing 2, 3, and 4 per cent. copper a campling variation of 5 lb. metal per ton of ore should be made before reaching the sample grinder.

Mining World, November 14, 1908.—The first installment of a paper on the Coeur d'Alene mining district, Idaho, by Dr. J. P. Rowe, appears in this number.

The principal producing portion of the district is wholly within Shoshone County. The axis of the Coeur d'Alene Mountains borders the district on the east, and nearly all the present profitable mining is done on the western slope of the Coeur d'Alene Mountains and on the north side of the south fork of the Coeur d'Alene River. The district east and west extends 20 miles north and 11½ miles. The producing territory is being constantly added to. Good roads, plentiful water, and good railroad service are features of the district.

Many of the best producing mines are worked to a depth of 2,000 feet by the tunnel method. Gravity alone is used for draining many of the mines and for handling the ore, although in the longer tunnels electric power is installed.

A prospector named Thomas Irwin located a quartz claim near the Mullan road, a few miles east of Kellogg, in 1878. Next year the famous Prichard Creek was discovered. Three years later placer gold was found on Prichard, and many claims, including the Widow, were staked. The year 1884 saw a general gold-seekers' rush. In a few months the town of Eagle sprang into being, trails were made to the Northern Pacific Railroad, and telegraphic communication was established. Later, the town of Murray became the centre of placer mining. Near it were the rich Widow, Gillette, and Myrtle claims.

In 1884 the town of Wallace (then known as Placer Centre) was founded, and some of the best silver-lead mines of the south side were located, including the Gold Hunter, the Helena-Frisco, and part of the Hecla. The next year witnessed the discovery of the famous Bunker Hill and Sullivan mines. From early in 1886 crowds from Murray and other outside towns flocked to the lead-silver district, especially to the country around Warden and Kellogg. The Bunker Hill and Sullivan ore was at that time hauled by wagons, boat, and rail to Helena, Mont.

In 1890 the beach gravels near Murray were worked vigorously. Narrow gauge and standard gauge lines had now entered the camps, and the larger mines operated their own concentrators. During the period 1892-4 most of the mines were closed on account of labor troubles and high freight rates. In 1898 many mines were consolidated by the Federal Mining and Smelting Company. The Hercules mine showed up rich ore in 1901, and made millionaires of several of the heaviest stockholders.

The Snowstorm copper mine was developed in 1903. Since then the district has grown steadily.

Mining Science, November 12, 1908.—An article of a series dscribing the Boston Consolidated Company's concentrating plant appears in this issue. The plant is situated at Garfield, Utah. Nissen individual-mortar stamps, installed in batteries of 4 weighing 1,500 lb., 6-inch drop, 106 to the minute, discharge through 26-mesh screens. The ore is crushed to ½ mm. particles before it passes the screens. The pulp is run into four 3-compartment spitzkasten, the overflow from the last compartment going to 12 Callow tanks. The concentrating equipment consists of two rows, 11 in each row, of No. 5 Wilfley tables, set head to head, receiving classiged feed; 12 Callow tanks, one No. 5 Wilfley table, and 17 Johnston suspended vanners complete the equipment.

PERSONAL AND GENERAL.

Mr. John E. Hardman has returned to Montreal after a prolonged absence on business connected with Canada Iron Corporation, Limited.

Mr. A. A. Cole, mining engineer to the T. & N. O. Commission, has thoroughly recovered from his recent illness.

Mr. A. P. Scott has resigned the position of chief chemist for the Dominion Iron & Steel Company, Sydney, N.S., to accept an appointment as metallurgist to the General Electric Company at Schenectady, N.Y. Mr. Scott did brilliant work in connection with Steel vs. Coal lawsuit.

Mr. G. H. Gillespie, now of Madoc, Ont., has returned from New York.

Dr. W. G. Miller, president of the Canadian Mining Institute, has been nominated by the Montreal branch as president for the year beginning March, 1909.

It is reported that Mr. James Gayley, first vice-president of the U. S. Steel Corporation, has tendered his resignation of that position, and that he will be succeeded by an officer of the Carnegie Steel Company. Ill-health is the cause of Mr. Gayley's resignation.

Mr. J. Parke Channing has been elected a director of the Kerr Lake Mining Co., in place of Mr. J. A. Jacobs.

Announcement is made that a law partnership has been formed between Mr. Edwin W. Kearney, of Haileybury, and Mr. E. Ainslie Wright, B.A., of Renfrew, to succeed to the practice of the late Harvey D. Graham. The new firm will be known as Graham, Kearney & Wright, and will continue to carry on a general law practice with permanent offices in the Graham-Hennessy Block, Haileybury, Ont.

Mr. H. Gardner, of London, Eng., one of the largest shareholders in the Granby Company, was a visitor in Phoenix for a couple of days last week, being shown through the mines by Manager A. B. W. Hodges. Mr. Gardner is in charge of the London office of the American Metal Co., which handles a large amount of Granby copper, Mr. Jacob Longcloth being president of both it and the Granby Company. Mr. Gardner is also largely interested in Montana and California mining, and is combining business with pleasure in a tour of the properties. He is accompanied by Mrs. Gardner.

Mr. Frederic Keffer, consulting engineer of the B. C. Copper Co., with a staff of assistants, was engaged for ten days this month making a complete examination of the Rawhide and Brooklyn mines of the Dominion

Copper Company. The examination has been most exhaustive, and samples for assaying have been taken from every lead in each of the properties. Previous to commencing the work here the Sunset mine, in Deadwood camp, and the Mountain Rose, in Summit camp, were thoroughly examined, so that in concluding the investigation at the Rawhide and Brooklyn Mr. Keffer was able to compile a detailed report on the Dominion Company's mines.

Notice has been given that after November 1st, 1908, the headquarters of the Canadian Mining Institute and the library of the Institute will be Rooms 3 and 4, Windsor Hotel, Montreal.

The fragility of incandescent gas mantles is a serious drawback to their use, but a more durable fabric seems to have resulted at last from the experiments of German chemists. The mantles now so familiar have a tissue of cotton or ramie on which oxides of thorium and cerium have been precipitated. Attempts to use other natural fibers have failed, and the successful new material is an artificial silk made by dissolving cellulose in ammoniate of copper. This silk mantle takes up thorium nitrate, which ammonia changes in the fiber to hydroxide of thorium. The thorium silk does not absorb moisture like the old mantles, and it has many times as great resistance to shock.

Powdered sulphur mixed with oil is claimed to have frequently relieved hot bearings in steamship machinery, but a lubricant much stronger still is sulphuric acid. On one occasion, after repeated trouble from heating, the dilute acid was allowed to drip slowly upon the working bearing. In half an hour the part was cooled, when the acid was washed out, and the ordinary oil was applied. The cure was permanent.

Slag Cement.—A material equal to the best Portland cement is now claimed from blast-furnace slag as a product of the Cowper-Coles process. The slag is taken while still molten and raised to greater heat by means of an electric resistance furnace, the necessary amount of chalk being added, and then certain reactions are brought about by electrolysis. High-grade cement is thus obtained at very low cost.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay, Nov. 20.—St. Lawrence Shipments.—With this week the 1908 season closes for the St. Lawrence. Notwithstanding all the difficulties that have been met with from forest fires and fog, the start obtained through the early opening of navigation has been maintained, and shipments will be in excess of any previous season. The Dominion Coal Company's shipments will total 1,340,000 tons, which is about 225,000 tons greater than last year.

Steel-Coal.—At the time of writing, it is supposed that the Steel-Coal appeal is being heard before the Privy Council in London. Before this issue of the Journal appears it is possible that we may know the result of this protracted legislation. The Montreal Star humorously states that the latest news from London is that Mr. James Ross says, "We will win," and Mr. Plummer says, "We will win." If these gentlemen made the remarks attributed to them, their grammar must have fallen on evil times.

U. M. F. A. vs. P. W. A.—Mr. John Moffatt, the Grand Secretary of the P. W. A., has been committed to the Supreme Court on a charge of perjury, at the instance of the partisans of U. M. F. A. in this neighborhood. The charge appears to be one of technical inaccuracy in an affidavit made by Mr. Moffatt in connection with the injunction which the U. M. F. A. obtained against the officers of the Grand Council. The trial is to take place on the 26th November, this date having been fixed in order that the Court might be acquainted with the judgment of the Supreme Court in the matter of the appeal of the U. M. W. A. against Judge Drysdale's dissolution of the injunction referred to. The full bench in Halifax unanimously dismissed the appeal. A large portion of the evidence in the perjury charge is identical with the evidence given in the appeal against the dissolution of the injunction.

From the rather mixed explanation just given it will be seen that a good deal of litigation is going on between laborites down here. It may eventually dawn upon the members of the miners' unions that paying lawyers is an expensive game, to which, like the making of books, there is no end. It looks as though the U. M. W. A., having failed in their attempt to get hold of the defense fund of the P. W. A., are determined to wasate it in legal fees.

Elections and Trade.—The Halifax Herald is surprised that there should be a depression in the coal trade after Mr. E. M. Macdonald's promises before the elections, saying that this gentleman had claimed all credit for the prosperity of the coal trade in Pictou. That may be, but is it not a little ridiculous for any political party to claim credit for prosperity or to be blamed for the opposite state of affairs? Under the representative form of government that obtains in Canada, as in other parts of the British Empire, prosperity or otherwise is not a matter of governments. It is a matter of the application of the laws of supply and demand. At election times all kinds of promises and threats are exchanged, and the direst forebodings are mixed with the most roseate prophecies according as one's political sympathies may tend. Yet the steady development of the nation goes along unchecked. Canada has not prospered during this past decade because her government has been Liberal or Conservative. She has prospered because she has drawn nearer and nearer to the glorious destiny reserved for her, and no matter who had been in power, this period in her history could not have been delayed any longer. This is a cardinal principle of British institutions. No matter what the nature of the administration, in the end the policy of the country remains immutable. Around election times the opposing candidates revile each other, and the newspapers become reminiscent of the "Eatanswill Gazette." But, after all, the Government does not do anything foolish or ill-advised. That is why most people are amused rather than impressed by such vaporings as were indulged in by the Halifax Herald regarding Norwegian shipping and the desperate straits of the schooner captains. Should any responsible Cabinet be so foolish as to act on the Herald's advice and immediately and violently upset the principal industry of the province, the Herald would be the first to cry out, and the usual colored headlines would be in evidence.

The Herald is not the only sinner, for its bitter rival (on paper), the Halifax Chronicle, has just received a well-deserved slating from the P. W. A. lodges. This latter paper made some very uncalled-for remarks on the result of the Cape Breton elections, stating that the miners were ungrateful, and had "stabbed their best friends in the back." This was because the Liberal candidate was defeated. Now, what right has any member of Parliament to pose as a special friend of any section of his constituency? He is in Parliament to represent his constituency, not to obtain favors for them. The statements made by various members of Parliament that they have obtained such-and-such benefits for their constituents, such as a postoffice, a wharf, or other public conveniences, betray a perverted sense of political duties. It used to be understood that members of Parliament were sent to the legislature to make laws and decide the policy of the country, not to act as a sort of glorified parish council debating about the parish pump. It is a sad fact to admit, but somehow the byword, "to the victor belongs the spoils," is firmly fixed in our political ideals.

Rescue Apparatus.—With our friends in the United States, to think is often to act. It is not very long since the three foreign experts made their report on the conditions in American mines, and it is only a short time since the Government's Central Rescue Station was erected in Pittsburg. In the past month, however, three serious fires have been fought successfully by men wearing the Draeger apparatus. The fires occurred in the Greensburg No. 1 Mine of the Keystone Coal & Coke Co.; the Hazel Mine of the Pittsburgg-Buffalo Co., and in the No. 1 Mine of the Washington Coal & Coke Co. The fires in the Washington Company's mine and in the mine of the Pittsburgh-Buffalo Co. were fought by men from the Government station. Further details are not to hand, but evidently the Pittsburgh station has soon got down to real business.

NEW BRUNSWICK.

The Canada Iron Corporation has lately taken over extensive Vanadian iron foundries, together with mining interests of the Drummonds. Mr. J. J. Drummond, of the above-mentioned corporation, accompanied by Mr. W. F. C. Parsons, chief mining engineer at Londonderry, N.S., was in St. John on the 17th of November, and on the following day left for Fredericton to hold a conference with the Provincial Government relative to the construction of the railway which the company intends building from their Gloucester iron deposit to Bathurst, the length of the road to be about twenty-five miles, with 80-pound rails, and of the best construction. Mr. Drummond recently interviewed Mr. O. Turgeon, M.P., concerning improvements at the entrance of Bathurst harbour, and expressed a hope that the Government would undertake the necessary work.

Relative to the merger herein referred to, Mr. Drummond denied the statement that the Drumond interests had been sold to an English syndicate. Five of the old directors were on the Board of the new corporation, and four new English capitalists were added. The control remains in Canada.

The corporation's capital si $8,500,000, and would likely be increased to $10,000,000.

Among the concerns included in the merger, Mr. Drummond mentioned the following: The Londonderry Iron and Mining Company; the Canadian Iron and Foundries Company, with plant at Londonderry; The Annapolis Iron Mines; foundries at Three Rivers, Montreal, Hamilton, St. Thomas, and Wort William; Canadian Iron Furnace Co., including the Radnor Furnaces, P.Q.; the Midland Ontario Blast Furnaces; the Drummond Char coal Furnaces, and the Georgian Bay Engineering Works. The corporation had also an interest in the Bathurst properties, the Drummond Mines at Cobalt, and Bessemer Iron Mines in Hastings County, Ontario, and other mines.

Mr. Drummond states also that a number of men are at work at the Gloucester mines uncovering the ore, and it is hoped to be able to start on a much larger scale in the spring. Immediately proper facilities are provided, the company will begin to ship ore, and will in due time establish a blast furnace at the mines.

It has been learned that the Local Government will consider favorably the matter placed before Premier Hazen by Mr. Drummond.

A party of engineers is now at work on the preliminary survey, and in the event of the grants being obtained, the final survey will be made this winter. The mines will in all probability be opened up in the spring, and ore will likely be ready for shipment by the time the railway is completed.

Upon trade conditions depends the development of the mines, and should these prove satisfactory, ore wil in the course of time be smelted on the spot. It is not the intention that the business proceed like in the pulp industry, in which the raw material is being shipped away and outsiders allowed to reap the profits of manufacturing

Mr. G. W. Ganong, ex-M.P. for Charlotte County, is interested in a copper property near Springfield, on the New Brunswick Coal and Railway Company's line. A seam of copper eight feet wide, which can be treated at but little cost has been opened up. Associated with Mr. Ganong in the venture are two Colorado mining men. Work has been suspended until the spring.

ONTARIO.

Cobalt, Nov. 21.—A topic that is being discussed on the street corners is Professor Hidden's break about Crown Reserve. Prof. Hidden stated that a hose had been played on the face of the vein for obvious purposes. Mr. Cohen denies this. Some one in Montreal and some one else here put up money to prove that Hidden is wrong. The Crown Reserve people claim that nothing is hidden. Hidden claims that all things are Hidden. And so on.

Cobalt is to have a daily paper. The "Cobalt Nugget" is undertaking to appear every 24 hours.

The Chambers-Ferland has installed an air compressor purchased from the O'Brien mine. A contrast has been made with the American Smelting and Reduction Company of Denver for ore under 1,000 ounces; 250 feet of drifting is the amount done up to date at the 100-foot level.

Andrew Osman and John Aha, two Finlanders, were killed at the Beaver Mine on the evening of Monday, November 16th. While they were being lowered in the bucket the bucket tipped and both men were hurled to the bottom of the shaft. Both were killed instantly. A boy of seventeen years of age was running the hoist.

Montreal River.—During the latter part of October your correspondent left Latchford for Elk Lake city. The journey takes ten hours, and is broken by three portages, none of which exceeds half a mile. Pork Rapid portage, about a third of a mile long, has a tramway for freight. On the other two portages freight is hauled by cart or sleigh. At Pork Rapid is a good eating-house. The return journey took eight hours.

The boats were loaded with provisions and supplies. Little machinery was visible. Between Elk Lake City and its sister city, Smythe, on the west side of the lake, only 100 yards of water intervene. Both settlements are well situated. The townsites are so placed as to secure good drainage and plentiful water. There are four comfortable, well heated, clean hotels. The grub is as good as can be found in any such places, and considerably better served than usual.

At the time of your correspondent's visit the snow was eight inches deep on the level. Consequently it was difficult to see the country to advantage.

Several properties, including the Otisse and Downey, were visited. The Downey lies half way between Elk Lake City and Silver Lake. Silver Lake is six miles from Elk Lake City.

No real mining was being done. At the Downey 30 or 40 bags of silver ore have been taken out. At the Otisse a considerable amount of trenching has been done. But now all energies were directed to putting up bunk-houses for the winter. Most of the buildings gave indications of being very substantial.

The general impression formed by your correspondent was that there is no such thing as a mine in the district. In fact, development work is hardly properly in swing. It will take at least six months of continuous work to get beyond the first stages of development. Unprejudiced visitors will admit that what this and the rest of the Montreal district offers is a fine chance for putting some money into investigating the promising surface showings. But nowhere is there anything that should be or can honestly be called a mine.

Investors should see that every cent of their money goes towards finding out what the Montreal River veins mean.

BRITISH COLUMBIA.

Rossland.—Mining has been quiet but steady throughout this district for the past two weeks. Elections on both sides of the boundary line have withheld immediate action in several matters that were pending, but now that the vacant offices have been filled those behind the mining industry here can put their plans into operation, well knowing what political interests they will have to deal with for several years to come.

The operations at the big mines during the past fortnight were along the regular lines, and a steady output was maintained. The tunnel being driven by the Le Roi No. 2, Ltd., on the Surprise claim is being rapidly bored. In this adit a new record for driving has been made for the camp. Messrs. Sexton, Swanson, Piper, and Jacobson, who have the work in hand, beginning October 5th reached the 180-foot mark on November 5th. They used one machine drill, working two shifts, and did their own blasting, etc.

The Centre Star during the last couple of weeks has shipped 3,700 to 3,800 tons per week, the Le Roi 1,600 to 1,900 tons, and the Le Roi No. 2, Ltd., from 400 to 600 tons, making the average weekly shipments a little over 6,000 tons per week. The average shipments from the camp are heavier than they have been for some time.

Among the small mines, the St. Elmo and I. X. L. appear on the shipping list, 3 35ton car of select ore having been shipped from the St. Elma to the smelter and a 3-ton shipment from the I. X. L. A considerable quantity of gold-bearing ore was taken from the I. X. L. in the early days, but the main lead was lost, and although several lessees have spent time and money digging for it, they have received but little reward for their labor. The ore is of an altogether different formation from that found in the Le Roi and other mines, but a few paces away being a quartzite and carrying gold both in a free state and associated with a base metal. No one would be surprised any day to hear that some one who had leased either the I. X. L. or O. K. mines had opened a duplicate of the rich pockets encountered in these mines in the early days, for all are confident that the main ore body is still to be located in the heart of the O. K. mountain.

PHOENIX.—Nothing unusual has happened in this district for several weeks. In Dominion Copper affairs there is very little that is new, and it is not expected that any important movement will take place until the reorganization proceedings have been carried through.

The Granby mines, the Mother Lode, and Oro Denoro of the British Columbia Copper Co., and the Snowshoe and Phoenix Amalgamated of the Consolidated M. & S. Co., are the only properties shipping at present. District shipments are being maintained at 34,000 to 35,000 tons per week. For the week ending November 14th the shipments were: Granby, 20,037 tons; Mother Lode, 11,566; Oro Denoro, 950; Snowshoe, 2,800. Including these shipments, which amount to 35,353 tons, the output of the district totals up 1,239,292 tons.

Henry Bahrs and associates have taken up the option on the Golden Zone group recently dropped by men interested in the Daly Reduction Co. Mr. Bahrs is now in Boston working on this deal. The Golden Zone group comprises the Golden Zone, Irish Boy, British Columbia, and Silver Bell claims. The showing on these claims is much similar to the ore found on the Nickel Plate group, the ore carrying gold, silver, and some nickel and cobalt. The work so far done on the claims has been in a development way, and consists of open cuts, glory hole and two shafts 35 and 50 feet in depth. A five-stamp mill was but lately installed at the property, which may be used for mill tests at certain periods of the year. Just now this mill is not in operation, owing to scarcity of water.

Development on the Bruce mine is giving good results. There is a splendid showing of chalcopyrite on the property carrying gold in a paying quantity.

Nelson.—The wonderful water power that is available at Bonnington Falls, and which is destined to play an important part in the future of the mining industry of Southeastern British Columbia, is now making its might felt in this district, and the machinery at the Silver King and Queen Victoria mines will soon be operated by electrical energy from the power plants on the Kootenay River.

The West Kootenay Power & Light Co. is developing 30,000 horsepower in two plants at Bonnington Falls, which is distributed over heavy voltage lines to Trail, Rossland, Grand Forks, Phoenix, Greenwood, and Nelson.

The City of Nelson also has an up-to-date power plant situated above the plants of the West Kootenay Co., and in addition to lightin gthe City of Nelson are competing with the West Kootenay Co. for the business of the mines.

The Van-Roi Co. are planning to do 1,000 feet of tunnelling and development. Work will be begun in the near future.

Development at the Ymir mines is being prosecuted in the direction of the big lead that it is thought lies beyond the old vein and farther in than the short section of vein recently uncovered 800 feet northwest of the old workings. The discovery of large and small fragments of "float" above the hill from the old workings led to the hypothesis that a large vein existed in the unexplored ground above the mine, and work carried out along these lines has given most encouraging results. It is expected that a new and valuable ore body will be opened up before the work has progressed much farther. The 80-stamp mill is capable of handling a large tonnage of ore; in one year the company having crushed 69,505 tons, from which a profit was derived of $40,000. Further working costs are expected to appropriate $4 per ton.

Vancouver.—A new seam of good quality coking coal has been opened up in the Bulkley district, about five miles from Telkwa. This seam is forty feet thick.

The Iron Mask, the leading mine of Kamloops district, has been disposed of to Minnesota capitalists. This mine has not been working for a couple of years, on account, it is stated, of financial difficulties. The showing of ore in the mine is very favorable, and there is an up-to-date hoisting and air compressing plant on the property. Upon the Iron Mask, to a great extent, rests the future of copper mining in Kamloops district.

George Patterson, an old prospector from the Yukon, recently took up a homestead near Sedgewick, Alberta, and the prospecting fever being still strong within him, he dug around and found a big deposit of auriferous gravel on his place, assays from which gave from $6 to $30 per ton. It is supposed that the deposit is of glacial origin. There is considerable excitement over the find, but considerable work will have to be done before the true value of the discovery will be known.

GENERAL MINING NEWS.

NOVA SCOTIA.

Halifax, N.S., Nov.10.—The transfer of the Drummond Iron Ore properties at Londonderry, Torbrook, and Bathurst to a wealthy English syndicate, headed by Sir James Heath, has been consummated, and very shortly the blast furnaces at Londonderry will be put in operation again to test the quality of the Bathurst ores. This is good news for Londonderry, and this section of Colchester, as the shutting down of the blast furnaces has caused general depression in the Colchester mining town and surrounding districts.

Sydney, Nov. 17.—It is reported that McKenzie & Mann are making an effort to purchase the Mabou coal mines at Inverness. These are conceded to be superior to any in Nova Scotia as to quality. The present owners are handicapped through lack of financial backing, and once this past summer were compelled to close the mine for a time, and at present it is only working on half time.

McKenzie & Mann own the Inverness Railway, which branches from the Intercolonial and runs past the Mabou deposits, and should they become purchasers, they could afford through superior shipping facilities to sell their product much cheaper than the present syndicate.

Halifax.—The Eastern Trust Co., receivers of the Boston Richardson Mining Co., have, as a result of the operation of the mine for the month of October, received a brick of gold weighing 579 ounces.

Halifax, Nov. 20.—With the sailing of the steamer Ocean from Sydney on Friday next the Dominion Coal Company's shipments up the St. Lawrence will discontinue for the season. The total quantity going in that direction this year was 1,345,000 tons, inclusive of a shipment of next Friday, an increase of about 200,000 tons over last season.

ONTARIO.

Craigmont.—Operations have been resumed at the plant of the Canada Corundum Company, at Craigmont, after a shut-down of some eleven months. The entire property of the Canada Corundum Company has been leased on a royalty basis to the Manufacturers' Corundum Company, Ltd., a corporation organized by Mr. D. A. Brebner, late secretary-treasurer of the Canada Corundum Company. The plant will for the present be run on a 12-hour shift, and with the improvement of business conditions in the United States a ready demand for the company's product is being met.

Cobalt.—During the month of October the La Rose Consolidated Mines shipped 17 cars of ore from their mine. Out of these cars five of them were high-grade, and the remainder were of a medium or lower grade. At the main La Rose mine a force of 170 men are engaged in active mining operations.

On the Violet property a force of ten men is engaged in surface prospecting. Several trenches have been dug, and up to date six well-defined veins have been caught. These will run from one to six inches in width of calcite. It is quite probable that a new shaft will be started on the property during the coming winter.

The only work being done at the University mine is the sinking of a new shaft. This shaft was sunk on three small veins, whose continued width made five inches, and the ore carries native silver. The shaft is down 45 feet, and will likely reach the 100-foot level before any drifts are driven on it. Only one machine is engaged in this work, and a force of twelve men are employed on the property.

During October the Nipissing Company mined ore of an estimated value of $121,445, and shipped ore of a nestimated value of $127,518.

The most important events of the month included the cutting of three cross veins on the 145-foot level of the Kendall; favorable prospecting developments in the diabase on R. L. 305 and R. L. 408; and the increased possibilities of cutting the La Rose vein at the Promise shaft, in view of recent developments by a neighboring company.

A recent trainload, consisting of about 600 tons of silver ore shipped from various parts of Cobalt, consigned to the American Smelting and Refining Company, Denver, Col., routed via T. & N. O. Railway to North Bay, Canadian Pacific Railway to St. Paul, in connection with the Chicago, Burlington & Quincy Railway, made the fastest time that has ever been accomplished on freight between these two points. The time occupied in transit was only four days and twenty-two and a half hours, this as against time via other routes of eight days.

ALBERTA.

Calgary, Alta., Nov. 18.—When the matter is taken up in earnest, it is believed a considerable supply of petroleum will be produced in Alberta.

From the American boundary on the south to Lake Athabasca, several hundred miles north of Edmonton, there are signs that the underlying rock is saturated with petroleum, while along the Athabasca River the deposits appear at or near the surface. Natural gas and oil pour out of the river banks and the bed of the stream for over 100 miles.

Near Pincher Creek some successful oil and gas well have been bored, and the Western Oil & Coal Consolidated, which has leased 13,000 acres of the most promising land surrounding that town, is now actively engaged in drilling for both oil and natural gas.

BRITISH COLUMBIA.

Kaslo.—At the Reco mine 4,000 sacks of ore are ready for shipment. As soon as rawhiding commences, shipments to the Trail smelter will be started.

Victoria.—The Daily Colonist says: "What ought to have a stimulating effect on mining affairs in this province is the announcement that Le Roi No. 2 mine, at Rossland, has declared another dividend, making a total of six shilling a share for 1908. This property is making an excellent showing, which is indicated by the fact that the shares have made a further advance in price on the London market, and the management is to be congratulated."

Nelson. Electric power from Bonnington Falls is being installed at the Silver King mine, nine miles from Nelson. Power is also to be installed at the Queen Victoria mine.

Nelson, Nov. 14.—While the principal feature in the mining in the Boundary is the pushing forward of the development work upon the Phoenix Amalgamated, belonging to the Consolidated Co. of Trail, where the owners expect confidently to have a mine equalling the Granby in point of capacity and while in Rossland there is steady prosecution of work upon the older properties and a good deal of leasing going forward in some of the lesser mines, in the Slocan the activity is still marked. Sandon is again resuming something of her old aspect with the prosperity derived from the working of the Whitewater and other mines. On Slocan Lake the Vancouver, while not shipping to any extent, is steadily developing. The site for the new mill there has been graded and preparations made for its erection in the spring. On Kootenay River a power line has been brought into the Queen Victoria mine where now nearly one hundred miners are employed and on the Granite nearly opposite the mill has recently been running some very good ore.

The alterations to the Bluebell mill have been completed and the mine is now in a position to maintain a large output. A new mill is being projected to work conjunctly the Mother Lode and Kootenay Belle, and a larger mill is being planned for the Nugget, while at the Queen in the early spring a

cyanide plant will be put in. In the meanwhile a two mile flume has just been completed, insuring the present plant against any lack of water. A power line 25 miles long is being surveyed to connect the Sheep Creek properties with the main line of the West Kootenay Power Company.

Kalso.—The Consolidated Mining and Smelting Company is reported to be after the Ivanhoe mine at Sandon. The Ivanhoe comprises a group of twenty-six claims, lying north of the Slocan Star. It shipped for years, but has been closed since 1905. The ore is composed of zinc-blende and galena.

Nelson.—With the beginning of winter on the higher slopes of the mountains properties which have been developing all summer are now beginning to ship under more advantageous conditions. While this is particularly true of the Slocan, other properties in Rossland and in the Boundary are also coming to the front as shippers.

The event of the week is the proving of a parallel lead on the Nugent mine on Sheep Creek. The Sheep Creek district hardly one year old and which has now an output of close on 700 tons weekly is negotiating for power to run its properties on a more economical basis.

In Rossland the Silver Belle mine, not shipping since 1896, is again to the front, while the I.X.L., an old Spokane proposition is again under lease. The Centre Star mine with a shipment of 4,677 tons for this week is a record, while the Trail smelter with its receipts of 9,953 tons has again established a record.

YUKON.

Vancouver, Nov. 7.—"Provided circumstances warrant we will next season complete construction of the spur from the main line into the mineral zone of the White Horse copper camp; seven miles, or half of this road, was built this summer." This statement was made by A. L. Berdoe, general manager of the White Pass and Yukon route.

"This season we constructed the heaviest portion of this spur, and carried it through some distance beyond the Arctic Chief mine, and to a property known as the Best Chance. Beyond that point the work is all light, and I believe that inside of two months the rails can be put down on the remainder of the spur. The road built this season was exceptionally heavy, as we had to contend with large rock cuts and muskegs. The work was performed in a thorough manner, and when operations were stopped on September 15 we had really done more than we expected to this year.

"At Skagway ore bunkers with a capacity of 5,000 tons were built ready for service. These are loacted right off the end of Moore's wharf and ore-carrying steamers will be loaded directly from the bunkers.

"Despite the fact that the depression had its effect on mining activity as had also the low price of copper, I am very glad that our company decided to build a portion of the spur last summer, for the reason that it was possible for us to obtain plenty of labor, something we could not have done in any ordinary year.

"While the north suffered from the depression this year in common with the rest of the country I am certain that next year conditions will be much improved. Of course, where placer mining is carried on with dredges operators are always one year behind the adoption of their plans owing to the fact that it takes that length of time to get their machinery and equipment built and laid down on the ground. This being the case it was not to be expected that any large new plants would be installed in the Yukon this year because in the fall of 1907 it was impossible to interest capital in even the certainty of a Klondike gold mine. Next year will be a prosperous one in the north."

More work is being done on Dominion Creek this winter than any time during the last two winters. Many lays are being worked and a large number of the owners are participating in the opening of the ground.

Upper Dominion is not so busy as that portion around Granville, but is far from being dead. Many claim owners and laymen wil have large dumps out by spring as evidence of their activity.

From No. 33 down there is much activity. Foley Bennett on 34 and 35 has 19 men on his ground, some working as laymen.

On 76, 80, 96 and 97 many men are engaged in mining as laymen. On 2 below Hufford, Campbell, McQueen and Mexican Jack are working a lay. A number of laymen also are working on Caron's ground on 10.

Frank Morrison, the heaviest Dominion operator, who did much open cutting during the summer, is preparing to operate in the coming summer on a larger scale than ever, but is not taking out dirt just now. Pete Rost, who also has become a big summer operator, is not working any men just now, but is on the creek and may be making a winter showing before long. Cason Brothers and Lemore & Modren were among those who made big open cuts on Dominion during the open season.

The claims mentioned individually in the foregoing are but a few of those working on Upper Dominion this winter, but enough to indicate there is something doing on the famous old creek.

Transferring Dredge.

The Yukon Gold Company will transfer one of its dredges now on a creek in the Atlin District to Dawson next season. A report to this effect is brought by a recent arrival from the Atlin district. It seems that the dredge, which has been in the Atlin district the last two or three seasons, has encountered too many boulders there. The impractibility of operation of that ground with a dredge is admitted, and the big machine is to be moved to the Dawson district, where gravel and other conditions are favorable.

Steam shovels have had better success in the Atlin district. When they encounter boulders they can work around them and leave them to be swung out of the way by derricks.

Hydraulic mining also is demonstrated to be a great success in the Atlin district. The ground is little if any frozen, and the season is long.

One Atlin operator adopted an unique means of digging a ditch several miles in length for bringing water to his property. He built a scow, launched it in a lake, mounted a steam shovel on the scow, and began digging along a certain grade from the lake toward his hydraulic location. By following the proper grade, he eventually made a first-class ditch with water running through it, and the steam shovel on the ground ready to assist in the work. The shovel was wrecked a time or two during the digging of the ditch but no serious damage resulted.

There was an explosion of fire damp in the Radboo mine at Hamm, Westphalia, Germany, November 12th, which probably will result in heavy loss of life. Already twenty-seven bodies have been brought to the surface and 300 men are still underground in grave peril. Four hundred miners were working in the pit at the time of the disaster. About 7 have been brought to the surface. Of these a majority are more or less injured, and one has since died. One hundred and fifty men are in shaft No. 2, and it is believed that all are doomed. Rescuers arrived from all directions and the work of getting below was at once organized. These efforts, however, were necesarily slow and attended with extreme difficulty. One of the shafts, together with its elevator cage, has been completely burned out. An improvised cage was sent down with a corps of rescuers, who made heroic efforts to reach their comrades. At one o'clock the fire had made such headway that the rescuers had to be called back to give way to the fire fighters, and the flames are still spreading. The vicinity of the mine is surrounded by police. A total of thirty-five bodies had been brought to the surface up to 4 o'clock this afternoon. Eighteen of the men who got out alive are severely injured. No hope is entertained for the 300 men still below ground.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

Monmouthshire coal-owners have decided to establish a rescue station.

The Hickleton Main colliery, near Doncaster, claims to have established a new record, in winding in one day of 13 hours 4,072 tons of coal from one shaft.

GERMANY.

The greatest mine disaster in many years occurred on Nov. 12th at the Radbod coal mine, near Hamm, Westphalia, an explosion being followed by a fire. Of 380 miners only about 40 escaped, many of them badly injured. Many dead bodies have ben taken out, the attempts to rescue the emtombed men being fruitless owing to the headway made by the fire.

RUSSIA.

There was a record output of iron ore in 1907, the total amounting to 4,227,419 tons exclusive of manganese ore exported from Poti, which were 881,322 tons, as compared with 464,016 tons the previous year. There was an increased demand in Germany for South Russian iron ore, 1,613,000 tons being shipped to that market, as against 535,000 tons in 1906. A marked increase was also shown in the production of pig iron.

SWEDEN.

Sweden is resorting to peat as a fuel in order to avoid dependence upon British coal. The country is stated to possess the largest peat deposits of any in the world, excepting Russia, and many inventions to utilize peat in the form of briquette and powder are being experimented with. The railways have been making trials with British coal, Swedish coal and peat, separately and mixed, to ascertain the most economical form of fuel. The total extent of the peat deposits is estimated at 8,000,000,000 tons.

AUSTRALASIA.

The coal in the Mackenzie River district, Queensland, is attracting attention. An examination to be made by diamond drill on a group of coal-prospecting areas extending for 25 square miles, near Tryphinia, on the Central Railway. The Mount Morgan Gold Mining Co. is interesting itself in exploration for coal near Bluff, where they have large buildings.

SOUTH AFRICA.

Increased activity at the diamond mines is reported. The Premier is making preparations for a greatly increased output and is installing a new plant capable of treating 15,000 loads per day. At the Voorspaed mine, Orange River Colony, washing operations have been begun with a new plant, the yield averaging about 20 carats per 100 loads.

A number of amalgamations of mines in the East Rand are being carried through. The Modderfontein Extension and Transvaal Lands and Mines Proprietary Syndicate have been merged, and among other amalgamations in process are those of the Chimes West and Benoni and of the Van Ryn Deep and Kleinfontein Deep.

UNITED STATES.

Mr. Samuel Newhouse, of Salt Lake, has purchased the Silver Peak Valcalda mines at Blair, Nev.

The Croesus Gold Mining and Milling Co., eperating the old Plumbago mine, near Alleghany, Sierra Co., Cal., is installing one of the most complete electric power plants in the State, and will considerably extend their workings.

The Fink furnace, which it is claimed will save half the cost of fuel, is to be tested on a commercial scale at Garfield, Utah, on the premises of the Boston Consolidated Mining Co., where a plant capable of treating 100 tons a day is being installed. The device consists of two revolving revedberatory furnaces, a central fire-box and a cluster of air pipes installed between the furnaces. By the revolution of the furnaces during the heating process it is claimed that new surfaces are constantly exposed where the heat blown in is most intense. It is asserted that blister copper can be produced with one melting, and that no coke will be required.

All the Arizona mines of prominence are very busy, and the total copper output for October is stated at 27,862,000 pounds. This was the largest monthly product this year, and from present indications Arizona will probably head the list as the largest producer of copper for the year 1908. For the first ten months of this year the Arizona production is estimated at 28,952,270 pounds more than that for Montana during same months. The Copper Queen mine is now the largest single producer with a monthly output of over 8,000,000 pounds.

The Greene mine is getting on its feet again, and for the month of October obtained an output of 3,854,000 pounds of copper, 95,506 ounces of silver and 698 ounces of gold. The new improvements are said to have resulted in reducing costs to less than to cents. The old plant was able to turn out 50,000,000 pounds of copper per annum, but the new management figure on a future production much larger than formerly.

Six men were instantly killed in a mine cage accident at the Ellsworth mine, Washington Co., Pa., on Nov. 16th. Owing to a break in the machinery the cage fell 285 feet to the bottom of the shaft.

INDIA.

The Indian Government has authorized the construction of a railway from the Gurakushinit Hill to Kalamati, where the Tata melting works will be established.

The production of coal was greater in 1907 than in any previous year. Bengal produced 9,993,548 long tons, valued at u2,208,091, and the output of the other provinces was 1,153,991 tons.

MEXICO.

There has been great activity in prospecting for and developing oil lands in different parts of Mexico, and several American syndicates have obtained options covering extensive tracts in the States of Tamaulipas, Vera Cruz and Chiapas. A number of drilling outfits have been brought from the United States.

COMPANY NOTES.

Mr. E. F. B. Johnston, K.C., presided at the meeting of shareholders of the Foster Cobalt Company, Nov. 5th, and explained the details of the report.

The company is said to have had three valuations on its ore dump, and these have varied from $15,000 to $50,000.

That part of the report dealing with the finances is as follows: "The present stock of ore on hand ready for shipment consists of about 30 tons of ore high in Cobalt, but low in silver. The prospects for early shipment of high grade ore is uncertain, depending entirely upon the results of the development indicated above.

"The results of some concentration done on ores from the dumps confirm the belief that these dumps contain values variously estimated at from $15,000 to $50,000. During the coming winter months when transportation is cheap, large quantities of this ore will be sent to the concentrator, where arrangements are in effect under terms distinctly favorable to the company."

Live Assets.

The financial statement submitted to the meeting showed the following live assets. Cash on hand and in bank, $17,342.18; due from smelter and ore sales, $24,185.42; accounts receivable, $476.44; supplies on hand, $2,379.56; total, $44,383.60. Also there is the ore in the ore house and in the dump variously estimated as worth sums up to $50,000. To offset the assets are wages due and accounts payable aggregating $4,454.74, so that deducting these, and valuing the ore at $18,000, the mine has $53,028.86 to the good, wherewith to operate, easily enough to run for another year if no further values are extracted.

The operating account for the year showed that $39,000 had been spent in ore extraction, and $37,000 in development, other expenses bringing total expense for the year up to $198,835.49. This is offset by $76,461.13 as the result of ore sales, $145 for rents, $1,099.60 from interest and exchange, and the balance $31,129.74 has come from the balance brought forward from last year of $82,624.13, reducing the present balance, as per balance sheet to $51,494.57.

Practically no objecting to the course of the directors were expressed at the meeting. The old board of directors was re-elected by acclamation.

The dividend on the Buffalo mine stock is now at the rate of 32 per cent. per annum. In a letter to the shareholders President Denison says that the increase would have occurred earlier, but he was waiting for a better silver market. The company apepars to have had the usual trouble crushing the ore, which is very hard, and Mr. Denison states that the capacity of the machinery did not come up to recent expectations. However, the new electric water pump, the cyanide plant, etc., have, in the president's words, "meant increased production at less expense and an increased revenue from what has been an accumulating, though heretofore idle, asset, namely, the ore going on the dump piles." The company will use the funds received from the distribution of the treasury stock to enlarge the concentrating and cyanide plants. The president says that dividends have ben paid from earnings, while development work progressed, and that there are now ore bodies in sight of greater value than he ever expected to see in this or any other Cobalt property.

A meeting of the bondholders of the Dominion Copper Co., Ltd., for which a receiver was apointed some time ago, will be held on November 30th at the office of Guggenheimer, Untermyer & Marshall, No. 37 Wall Street, to receive a report from the trustee of the bondholders as to the action which has been taken, and to consider such other matters as may be brought before the meeting.

The La Rose Mines, Ltd., makes the following preliminary statement of production and earnings for October:

	Tons.	Silver contents. Ounces.	Net value.
Shipments.	541	199,271	$88,890
On hand Oct. 31.	94	102,454	47,456
Total.	635	301,725	$137,346
Less on hand Sept. 30	142	106,287	49,930
October production	493	195,438	87,416
Estimated expenses..	...	.....	23,207
Net profit for October	...	.....	64,209

Total for June, July, August, September and October silver contains 1,230,180 ounces; net profit, $484,853.

The annual meeting of the Green-Meehan Mining Company was held on November 7th. It was explained that the reason work was stopped on the mine was because the values petered out, and the directors wished to wait to see how other mines succeeded in their experiments as to how much ore was to be got deeper down.

Whilst this explanation was accepted, it may be termed an explanation only by courtesy.

The work was stopped on December 15th, 1907, and preparations to continue it were started a week ago on information received, but not vertified, as to the ore to be found at a depth.

The money in the treasury will enable the company to keep working for some time. Two hundred thousand shares of stock were put in to operate the mine two months before the work stopped.

The shareholders were not satisfied with the reasons advanced as to why the work stopped, but E. B. Ryckman, the chairman, said they were the only reasons he had. They said that not sufficient effort had been made by the dicetors to carry on the worik.

An engineer was asked recently to go up and take charge of the mine. Ii ts three-quarters full of water, and the trench is two-thirds full. This water has been accumulating ever since work stopped. It is estimated that $200 will take it all out.

One director sold 14,000 shares to a friend, but of the 700,000 shares held by directors that is the only sale known.

The chairman was asked why the treaspry stock was not sold when it was around 170. He said the reason was that the expert said there was enough value in sight to run the mine, and they had made so much in the first couple of months that they decided not to sell.

There is about $25,000 worth of low grade ore now on the property.

Twenty-seven thousand dollars will be spent to see if any results are to be obtained from the mine.

The chairman said that the directors have spent $50,000 of their own money.

They expect to sink the shaft at an expense of $40 per foot.

At the annual meeting of shareholders of the Cobalt Townsite Mining Company, Limited, held at North Bay, a new board of directors was elected, consisting of Eric H. Rose, London, England; Thos. Plunkett, New York; Rupert Simpson, Simcoe, and W. R. P. Parker, Toronto. The new officers of the company who were elected were: President, W. R. P. Parker; vice-president, Rupert Simpson; treasurer, E. H. Rose.

The reports of the managing director and of the manager of the mine were received and considered, and were of a satisfactory nature.

It is said that there have been some recent strikes of unusual value on the property, and a strike on the Right of Way of a vein traced into the property of the Cobalt Townsite Company.

At a meeting of the directors of the Tretheway mine on November 13th it was decided to make a 10 per cent. distribution of profits on December 15th. The company will not adopt the practice of declaring dividends at stated intervals, but will disburse the profits among the shareholders whenever a sufficient surplus accumulates in the treasury.

The last dividend of $2 a share on Granby Consolidated will make $4 for the year.

The dividend record of Granby is as follows, on basis of $100 par value:

1908	$4	1905	$3
1907	9	1904	0
1906	12	1903	1

The initial payment was made December 16th, 1903.

STATISTICS AND RETURNS.

Returns to the Bureau of Mines show that the output of the metalliferous mines and works of the Province of Ontario for the nine months ending September 30th ,1908, was as follows:

		Value.
Arsenic, tons	464	$19,892
Cobalt, tons	480	80,623
Gold, oz.	2,504	40,797
Silver, oz.	12,223,834	6,141,090
Copper, tons	5,892	837,559
Nickel, tons	7,760	1,494,693
Iron Ore, tons	166,088	448,532
Iron Pyrites, tons	13,417	43,948
Pig Iron, tons	189,287	3,098,661

Shipments from the Cobalt mines during the period amounted to 18,325 tons, including 480 tons of concentrates. Arsenic in the above table represents only the quantity recovered by reduction works in Canada, and cobalt only the cobalt contents of shipments for which mine-owners received returns.

INTERCOLONIAL COAL CO.

Shipments, Oct., 1908	18,304
Shipments, Oct., 1907	19,973

CROW'S NEST COLLIERIES.

The output of the Crow's Nest collieries for the week ending November 6th was 19,634 tons, a daily average of 3,272 tons.

The output of the Crow's Nest Pass Coal Company collieries for the weey ending November 20th was 19,927 tons, a daily average of 3,321 tons. Week ending November 22nd, 1907, 18,508 tons, a daily average of 3,085 tons.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp and those from January 1st to date:

	Week end. Nov. 7. Ore in lbs.	Since Jan 1. Ore in lbs.
Buffalo	104,000	1,916,950
*Coniagas	64,430	1,297,288
Crown Reserve	120,000	714,688
City of Cobalt	670,000	1,306,300
Foster	140,000	487,300
La Rose	197,000	7,528,970
McKinley-Darragh	285,000	2,859,770
Nova Scotia	40,000	487,675
Silver Cliff	46,100	98,100
Townsite	40,600	292,300
Temiscaming	63,360	994,980
T. & H. B.	60,000	2,338,666
Tretheway	60,000	2,102,476

The total shipments for the week were 1,287,490 pounds, or 643 tons. Total shipments from Jan. 1 to date are 36,541,756 pounds, or 18,278 tons.

Following are the weekly shipments from Cobalt camp, and those from Jan. 1 to date:

	Week end. Nov. 14. Ore in lbs.	Since Jan. 1. Ore in lbs.
Chambers-Ferland	60,000	443,890
City of Cobalt	61,700	1,368,000
Kerr Lake	61,400	1,152,794
La Rose	395,500	7,924,470
Nispissing	293,740	3,235,350
O'Brien	255,180	6,101,337
T. & H. B.	60,000	2,193,666

The total shipments for the week were 1,187,520 pounds, or 593 tons. Total shipments from Jan. 1 to date are 39,251,056 pounds, or 18,627 tons.

COBALT ORE SHIPMENTS.

Fololwing are the weekly shipments from Cobalt camp and those from Jan. 1 to date:

The total shipments for the past week were 43,417 tons and for the year to date 1,601,151 tons.

GRANBY SMELTER RECEIPTS.

Grand Forks, B.C.

Granby	20,035	907,579

B. C. COPPER CO.'S RECEIPTS.

Greenwood, B.C.

Total	12,516	285,939

CONSOLIDATED CO.'S RECEIPTS.

Trail, B.C.

Total	7,223	281,012

LE ROI SMELTER RECEIPTS.

Northport, Wash.

Le Roi	2,017	68,526
Queen	27	864
Other Mines	298	6,119
Total	2,342	75,509

The total receipts at the various smelters for the past week were 42,116 tons and for the year to date 1,557,641 tons.

The output of pig iron in the United States will hardly exceed 15,500,000 tons for 1908. This is less than has been recorded since the year 1900. The output for 1907 was 25,781,361 tons.

The out put of copper from the Michigan mines for October is reported at 19,943,340 pounds, which is 736,385 pounds more than the September figures. Lake Superior production for the first ten months of this year is estimated at 188,030,129 pounds, as compared with 190,013,414 pounds returned for the same months last year.

Butte mines are estimated to have produced during October 28,864,410 pounds of copper, and for the first ten months of 1908 the total of 210,845,730 pounds. The Anaconda and Boston & Montana both did better than in September, and these two producers showed an output last month in the aggregate of over 15,000,000 pounds. Montana production since January is estimated at 13,591,477 pounds below that for the first ten months of last year, but at the recent rate of output the differences should be wiped out.

During the nine months ending with September the exports of ores and metals from the United States including the following:—

	1907.	1908.	Changes.
Aluminium, value	$259,984	285,711	I. $25,727
Copper, fine, lb.	280,056,017	520,609,477	I. 240,553,460
Copper in ore, etc., lb.	9,267,464	7,254,638	D. 2,012,826
Iron ore, tons	158,243	191,408	I. 33,165
Iron pig, tons	60,109	30,508	D. 29,601
Nickel metal, oxide, etc., lb.	6,979,881	8,026,950	I. 1,047,069
Quicksilver, lb.	345,297	185,089	D. 150,208
Spelter, lb.	785,498	4,556,301	I. 3,770,803
Zinc ore, tosn	13,991	21,056	I. 7,065
Zinc dross, lb.	16,520,771	13,555,081	D. 2,965,690

The following are the figures of German consumption of foreign copper for the months of January and September, 1908: Imports of copper, 122.55 tons; exports of copper, 6,393 tons; consumption of copper, 116,162 tons, as compared with consumption during the same period in 1907 of 87,480 tons.

Of the above quantity 112,829 tons were imported from the United States.

MARKET REPORTS.

Nov. 20.—Connellsville coke, f.o.b., ovens:—
Furnace coke, prompt, 5$1,75 to $1.85.
Foundry coke, pormpt, $2.15.

Metals.

Nov. 20.—Tin, Straits, 3.03 cents.
Copper, prime Lake, 14.4 to 14.5 cents.
Lake arsenical brands, 14.4 to 14.5 cents.
Electrolytic copper, 13.125 to 14.25 cents.
Copper wire, 15.75 cents.
Lead, 4.35 cents.
Spelter, 5.05 cents.
Sheet zinc, 7.5 cents.
Antimony, Cookson's, 8.25 cents.
Aluminium, 25 cents.
Nickel, 40 to 47 cents.
Platinum, $22.50 to $23.50 per ounce.
Bismuth, $1.75 per lb.
Quicksilver, $47 per 75-lb. flask.

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905. Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 500,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

CHAS. SIMISTER, General Superintendent.
J. D. HURD, General Manager.

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary, and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

Some Books of interest on Mining to be had from the Book Department of the Canadian Mining Journal, Toronto, Ont.

The Copper Mines of Lake Superior. By T. A. Rickard. An attractive volume of 165 pages, handsomely illustrated. The present work consists of a group of interesting articles in a revised and amplified form, which were originally published in the columns of The Engineering and Mining Journal during the latter part of 1904. Octavo, cloth. Price, $1.00.

The Chemistry of Cyanide Solutions Resulting from the Treatment of Ores. By J. C. Clennell. Price, 2.50.

Across the San Juan Mountains. By T. A. Rickard. A graphic description of a picturesque ride of 400 miles on horseback through the San Juan Mountains in South-western Colorado. The work is written in vigorous and buoyant style, and the information contained therein, while appealing specifically to the geologist, prospector, and mining engineer, will also prove of great interest and enjoyment to the general reader. Small quarto, cloth, ornamental covers and profusely illustrated. Price, $1.00.

Ore Deposits. A discussion republished from the Engineering and Mining Journal, containing the recent contributions on the origin of ores. By S. F. Emmons, W. H. Weed, F. L. Ransome, C. R. Van Hise, T. A. Rickard, and C. W. Purington. The matter originally published has been revised and amplified. A review of the subject by the Editor of the Engineering and Mining Journal is added. It is an up-to-date discussion of a subject which is of great interest to mining men. The book contains 100 pages. Cloth. $1.00.

Mineral Resources of Canada. An illustrated handbook giving a brief outline of the economic minerals of Canada, and sketching the mineral resources of each province. The book contains 140 pages, 32 color engravings of the most important minerals. The latest mineral Resource Map of the Dominion, showing the chief mineral deposits, is also included. No such work has been attempted in Canada before. This volume should be in the hands of every one interested in the mining industry. The price of this volume is extremely moderate. $1.00.

Minerals and How They Occur. By Willet G. Miller. Provincial Geologist, a volume of 250 pages, illustrated. This book is especially adapted to the prospector for minerals, as he must have a knowledge of mineralogy before he can properly understand the character of rocks and the effects which are produced on them by atmospheric and other agencies. If you are a prospector this is the work for you. Price, $1.00.

The Sampling and Estimation of Ore in a Mine. By T. A. Rickard. Sampling and mine valuation are eminently practical subjects, and in this work they are handled in detail by engineers and experts of the first rank, who have had world-wide experience in these matters. To students, mine directors, mining engineers, mine investors, and engineers generally, this volume will be found extremely useful. Octavo cloth, profusely illustrated. Price, $2.00.

Rocks and Rock Minerals. By L. V. Pirsson, Professor of Geology in Yale University, 414 pages. 74 figures, 36 full-page half-tone plates. Not all mining men have an intimate knowledge of petrology, or the science of rocks. Even those who have had the advantage of a college course find that only a small residue of what they learned adheres to them. Most text-books on the subjects are cast into forms that repel the lay reader. Hence it is not easy for the beginner to acquire the rudiments of the science. "Rocks and Rock Minerals" is an attempt to present the outlines of petrology in such a way as to give an intelligent idea of the subject to readers quite unacquainted with the microscopic standpoint. Rocks and rock minerals are dealt with entirely from a megascopic, or practical outdoors, point of view. The book before us attains the desired object of giving the reader a knowledge of rocks and rock minerals without recourse to the microscope. It is a very fair introduction to the study of geology generally. Part III., in which igneous, stratified, and metamorphic rocks are described, is an excellent treatise in itself. Simplicity is the keynote of the book. Cloth. Price, $2.50 net.

A History of Cobalt. During the summer of 1907 the Canadian Mining Journal published a beautiful illustrated souvenir volume. Included in this volume is a history of the early days of Cobalt. An excellent map of the district accompanies the book. Price, $1.00.

The Electric Furnace. By Alfred Stansfield, D.Sc., A.R.S.M., Professor of Metallurgy, McGill University. There has long been need of a good book on electric furnaces. The increased importance of the subject and the great value to metallurgy makes this book most timely. 211 pages (illustrated) 6 x 9 inches. Price, $2.00

Simple Mine Accounting. By David Wallace. A neat compact description of the simple methods of keeping mine accounts. Mr. Wallace is an expert mine accountant and in this book he outlines briefly and simply the kind of accounts and records which a small mine should keep. 64 pages, 6 x 9 inches, with bookkeeping forms. Price, $1.00.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

THE OFFICIAL MINING DIRECTORY OF MEXICO, 1908-1909

CALLE DEL ELISEO, 37, MEXICO, D. F.

EDITORS: JOHN R. SOUTHWORTH, F.R.C.S. and PERCY C. HOLMES.

"The Official Mining Directory of Mexico" is the 10th volume of the series of works, devoted to the propagation of knowledge concerning the resources of M exico, which has been issued from these effices under the authorization of the Mexican Government, each co py being duly impressed with the Federal Seal of the United States of Mexico.

The contents of the work comprise:

Alphabetically listed descriptions of over 1,500 M ining companies operating over 7,000 mining properties in Mexico. Only such companies as employ more than 20 men, or use power other than animal power, are listed.

The data given, in respect to these companies, is exemplified in the specimen shown on this sheet. It includes name of company, home office address, mine o ffice address, president, secretary, treasurer, directors, manager, superintendent, subordinate staff, where and when incorporated, capitalization, issued stock, par value of shares, additional financial data, names of m ines, number of claims, product, description of ore, description of geological formation, kind of power used , number of horsepower used, description of mine workings, capacity of treatment plant, cyanide plant, smelter , etc., number and weight of stamps, number of grinding mills, number of tube mills, number of concentrators, number of men employed, contemplated improvements, general remarks.

The volume is illustrated by over 200 photographs and maps, showing the leading mines, mills, smelters, and camps in the Republic.

Tables of utility to mining men, shippers and inv estors are given.

A Spanish-English glossary of Mining Terms make s the translation of letters from Mexican miners possible, where a dictionary would be valueless.

Preliminary to the actual directory, there are spec ial articles, written by competent Mexican and foreign authorities, on:

"The History of Mining in Mexico."

"Number and Geographical Distribution of Mines in Mexico."

"Foreign Investments in Mexican Mining Securiti es."

"Progress of the Metallurgy of Gold and Silver in Mexico."

"The Mexican Mining Chamber."

"The Mexican Mining Laws."

"The International Bureau of American Republics ."

The edition presented to your notice is in English, and contains 280 pages, measuring 13 inches by 10 inches, bound in chocolate colored cloth, with the title in gold lettering on side and back. Type and paper are of the finest quality. Price, $5.00, U.S. Cey., £1 1s. 0d. stg., M22., $10.00, Mex. Cey., Frs. 25, postpaid.

Copies of this excellent work may be had from the Book Department of Canaadian Mining Journal, Toronto

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERBEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

Westinghouse

Individual Motor-Drive for Mines

Leaving superior efficiency out of the question

two points strongly favoring Westinghouse motor-driven mine hoists and other apparatus, are the flexibility of location and simplicity of connection to the service supply, requiring only small wires, which may be readily located and extended or moved, with little trouble, as frequently as desired.

THE AMERICAN TUNNEL RECORD

During January, 1908 the No. 1, or River Portal Heading of the Gunnison Irrigation Tunnel, in Montrose County, Colorado, was advanced 440 feet through hard granite rock. This constitutes the best performance in tunnel-driving on record in the United States.

The tunnel is 12x10 feet in cross section, and when completed, will be the longest artificial underground waterway in the world (30,582 feet).

SULLIVAN ROCK DRILLS size "CD" (3 in.) were the machines used by the Government engineers in making this record. Sullivan Drills have been used exclusively on this tunnel since March, 1906.

RAND Mining and Industrial MACHINERY

Our new compressor catalog is now ready for circulation. This book contains over 100 pages of information of interest to mining and manufacturing men. Among the more important articles is one on the selection of a steam driven compressor. The questions of lubrication, air coolings and regulation are thoroughly dealt with, and all standard machines are listed.

Dry Concentration

ABSOLUTELY DUSTLESS

The Behrend System

THE Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on ores of all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

WRITE US FOR DESCRIPTIVE PAMPHLET.

and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLER

Provincial Geologist of Ontario, formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

CHRISTMAS.

The year that is just about to close has brought success to many a mining camp. From Nova Scotia to the Yukon we are receiving advices that warrant us in expecting largely increased annual outputs. Corporations and individuals have prospered.

The whole beauty of Christmas lies in bringing comfort and joy not only to the members of our own households, but to those whose ways are darkened with suffering and want. And no giving is more seemly, none brings more pure pleasure, than the giving that helps sick and suffering little children.

Our readers will notice in our advertising pages the plea of the Hospital for Sick Children. To the forceful eloquence of this plea we can add nothing beyond the statement that, in our belief, this is one of the noblest and most urgent of all humane institutions.

What better means of truly celebrating Christmas could be chosen by the mining committees of Ontario than in contributing according to their means to brightening the day for sick little cihldren!

MONTREAL RIVER.

There is a discouraging risk attached to any honest expression of opinion about a mining prospect. The most promising surface exposure may lead to nothing. Riches may lie in wait for him who follows a most unlikely outcrop.

But there are prospects and prospects. For instance, in the Nevada goldfields it is not unusual to sink through hundreds of feet of rhyolite before striking pay ore. Knowledge of the immediately surrounding country makes such ventures commercially possible. And there are many analogous cases in the mining districts of foreign countries.

It is well, however, to re-emphasize the plain truth about the Montreal River districts. The most authoritative opinions—here we do not refer to those that are appended to borkers' advertisements—when boiled down agree in all vital respects. These points of agreement may be set out in a few sentences.

The new silver region is worth spending money upon. Several of the properties appear to have exceptional potentialities. The expenditure of money in opening them needs no justification. It is good business.

On the other hand there is not one jot or tittle of common sense in paying hundreds of thousands of dollars for unproved claims. A calm view of the situation reveals at once that there is no basis for such prices. Small quantities of native silver, "strong" outcroppings of calcite, are not mines. Their value is negative, and must remain negative until many dollars are spent in clearing

ground, building roads, and putting in mining equipment. Therefore, it is simply nonsense to talk of selling or buying mines in the Montreal River districts. Let the ardent investor remember that fancy prices are permanent burdens.

Again, when 25 per cent. of your investment disappears in the brokers' pocket, it is not to be gainsaid that only 75 per cent. remains for developing the prospect into a mine. Now, if the stock that you buy is labelled "treasury stock" there is a fair chance of some of your money being applied to the development of the mine. If, however, your company is taking up a page or half a page, or even quarter of a page in the daily papers, it means that you are contributing your quota to an advertising bill amounting in some cases to more than $15,000 per month. This aids the pulp industry.

The happiest issue from your troubles as an investor (and perhaps the best in the long run) is to buy stock that is labelled promoters' stock, or is not labelled at all. You may then be morally certain that your money will not return to you after many days.

THE CONIAGAS MINES, LIMITED.

During the year ending October 31st, 1908, the Coniagas Mine, of Cobalt, Ont., yielded 1,444,229 ounces of silver at a cost of about 15.6 cents per ounce. Among the fortunate shareholders the sum of $440,000 was distributed in dividends. There is still, as will be seen from the statement on another page of this issue, a healthy balance left over.

It is gratifying to note that the ore in sight is estimated as carrying thirteen million ounces. In other words there is approximately enough ore developed to maintain production for four years with the present annual output doubled.

There will be, sooner or later, substantial profits reaped from the Company's smelter at Thorold. The concentrating mill at Cobalt has passed through its bilious period. The production of power has been cheapened by means of a gas producer. The mine is in good condition. Twelve of the forty acres held by the company, have been partly developed at a relatively low cost. The deepest level is only 150 feet and we have the official assertive that there is no diminution at that depth of the silver tenor of the ore, which, apparently averages about $230 to the ton.

We use the word "apparently" for due cause. The report, interesting as it necessarily is, leaves much to be desired. On account of the form into which the principal accounts are thrown it is impossible to determine anything but the total cost of all operations. The plans that accompany the report are clear and instructive.

The Coniagas Mines, Limited, as a corporation has made no apepal to the public. It has, from its inception, minded its own business efficiently. Its expanding operations mean employment for more Canadians and the addition of much clean money to the country's wealth.

SIR HENRY WILKINSON.

When, in the early "nineties" the Lake of the Woods began to attract men of all kinds and conditions, Lieutenant-General Sir Henry Wilkinson was already a picturesque integer of the group of mining men that foregathered at Rat Portage. His mine, the Regina, was one of the producers. However, it produced gold at a prohibitive cost.

Through thick and thin, through good report and evil report, Sir Henry stuck to his mine. Manager after manager failed to make it pay. Sir Henry, with that singular British admixture of tenacity and impracticality, stuck to his guns. We believe that his faith in his mine never waned for a day or an hour.

Sir Henry died at Kenora a few weeks ago. He will be sincerely mourned by all who know or had to do with him. A courteous gentleman, he was above reproach in all his dealings.

But his life was given a deeper color by the consistent frankness with which he professed and followed the teachings of the Christian religion.

Lieutenant-General Sir Henry Wilkinson fought a losing fight, with not one thought of surrender He fought cleanly and he fought steadfastly. What higher praise can any man merit!

RESCUE APPARATUS IN SICILY.

The use of breathing apparatus is every day becoming better known. In March, 1908, the Testasecca sulphur mine in the province of Caltanisetta, Sicily, developed a dangerous fire in the third level in a section where the sulphur ore was particularly rich. The usual course was to seal hermetically a part or the whole of the mine and wait for weeks or months until the fire died out. In this instance, however, although there was a delay of three weeks in waiting for the apparatus, it took only three days to extinguish the fire.

The rescue apparatus used was of the Westfalia type It was reported upon as being satisfactory except for the effect of the heavy fumes of sulphur dioxide upon the more sensitive parts. It will be admitted, however, that a test of this sort in a deep sulphur mine is about as searching a trial as can be imagined.

THE BOUNDARY DISTRICT.

Within the past nine years there have been more than seven million tons of ore shipped from the mines of the Boundary District, British Columbia. This year's shipments, amounting on November 21st to 1,274,966 tons, exceed the total for the year 1907

The largest individual contribution to the grand total of seven million tons is the Granby Mine of the Granby Consolidated. This mine shipped 65 per cent. of the total. Next in order comes the Mother Lode of

the British Columbia Copper Company, which has 20 per cent. to its credit.

It is most encouraging to be able to record largely increased mine outputs for the current year.

THE SKEENA RIVER DISTRICT.

Northern British Columbia is a country of vast distances and of rich promise. Of both the mineral and the agricultural possibilities of a great part of the immense region drained by the Skeena River, but little is known. What scant knowledge we have, however, indicates that there is room here for a whole generation of prospectors and settlers.

Mr. J. C. Gwillim's article, which appears in this issue of the Canadian Mining Journal, we commend to that restless brotherhood whose members are now and always searching for pastures new.

SKEENA RIVER DISTRICT.

By J. C. Gwillim.

The journey from Vancouver to Port Essington, or Prince Rupert, takes from forty to fifty hours. The trip is made on any of the many boats now calling in on their way to more northern ports. It is a voyage without a parallel in the world—so sheltered from the main Pacific ocean that there is seldom any seasickness. For half the way the eastern shores of Vancouver Island are followed quite closely, a scene of mountains, green islands and glittering seas, or arms of the sea, in every direction. Even now this passage presents an almost continuous succession of steamboats, far apart, but in the days to come, when this desirable land is peopled, and the fisheries, timber, farming lands, and mines are fully developed, there will be a sea-going traffic through these waters which may be greater than that of the Great Lakes at the present time.

Nearly all this traffic at present passes through Seymour Narrows, a channel that may some time be bridged. Through this pasage go all the Alaskan boats and fishing boats, also the new traffic between Prince Rupert and Vancouver.

After passing Vancouver Island the land and sea features change considerably. There is the same intermixture of land and water , but the land is more precipitous, and is clothed with a less generous tree growth. There is a general absence of soil; the nakedness of the hilly islands seems only clothed with moss and smaller trees; the beach is a water-mark on the rock which dips steeply into the sea, or a ragged reef-ribbed shallow.

Port Essington and Prince Rupert are both built on uneven, rocky lowlands. Everywhere there seems to be an absence of alluvium or soil; rain, rock, moss and wet beach impress one in the region round the mouth of the Skeena.

The Skeena, like the Fraser, drains a great district from the interior of British Columbia and descends swiftly through the Coast Ranges, but unlike the Fraser has practically no delta. The valley, even at tide water, is comparatively abrupt and narrow. The only flats are narrow, marginal strips, or island bars, covered with great conifers and cotton woods.

Until the present time of Grand Trunk Pacific construction, the Skeena has been the highway only of Indians, Hudson Bay Company boats, and placer miners.

Although the Hudson Bay Company has for years operated steamboats on this river for a distance of 170 miles, from Essington to Hazleton, it is no light undertaking to make the trip.

In Volume III. of the Canadian Mining Institute there is a paper by E. C. Musgrave upon "A Prospecting Trip in Northern America." Mr. Musgrave went to Hazleton by the old steamer Caledonia (now on the bars of the lower river). The trip up the river,, 170 miles, took about three weeks. One week was spent tied up to the bank waiting for the water to rise, the rest of the time in fighting the swift water, with much warping in the worst places.

Midway between Essington and Hazelton is Kitsalas Canyon, a narrow, crooked and short little jagged pair of passages, through a low rock obstruction. A water gauge at this place indicates when it is safe to make the passage, and often boats await the proper conditions of water level for many days.

Our own trip up the Skeena in August last was a lively one. We were hardly over three days from Essington to Hazelton Construction of the railway is proceeding at many points along the lower portion of theh river. The railway follows the narrow marginal flat, or cuts through bold rock promontories which are a part of the steeply rising ranges on that side of the river.

Much of the work of this first 100 miles out of Prince Rupert will be heavy and costly, with little local support after building.

Further up the river there are raised benches of greater extent and less rainfall. Much of this valley is said to belong to a wood pulp concesion, and a considerable amount of the most desirable bench lands is occupied by Indians. Nowhere in Canada, perhaps, is there a main highway and its traffic so largely influenced by its Indian population—a somewhat jealous people, also, who do not regard the changing order with much satisfaction.

Arrived at Hazelton, one finds it is a point of dispersion for other more remote places Although it has been for so long the starting point, and finishing point, of overland journeys to the interior, there seems to be no organized transportation

The chief means of travel is with pack-horses. These may be hired from the many Indians who traffic in horses and freight throughout the district.

Hazelton is hardly the centre of a productive district; it is more like the funnel entry to the Pacific coast from a great interior region full of possibilities in the agricultural and mining industries.

From Hazelton one can go northwards up the Kispyox and Skeent Valleys and into that little known land towards the Yukon; eastwards one hudred miles to the placer camps of Omenica; and beyond it, to the north, are the new Ingenica placers. South-eastwards is the Bulkeley Valley, on the route of the railway, and further south and east the wide belts of agriculture land in the Nechaco and other districts.

Concerning the agricultural possibilities of this region,

it may be said that the valleys appear eminently fitted for any crop where leaf or blade is chiefly required. Roots also do well. The natural vegetation is a matter of astonishment and also, sometimes, of vexation. No frost had damaged anything at Hazelton on Sept. 10th last, when we left.

Concerning the mineral resources, the district is one of great distances, and not yet much prospected excepting a few camps on the Telkwa river, which lies 60 to 80 miles south of Hazelton. Although the district or region as a whole is much easier to get about in than Kootenay, it has only a few trails and few inhabitants, all of whom are a long way from cheap and ready supplies. The main discoveries so far have been in the Babine mountains, 60 miles south of Hazelton, and in the Telkwa river basin, 60 to 80 or 90 miles south by trail from Hazelton Every pound of supplies is packed in to these places which makes operation a costly and troublesome business.

Although this district has been more spoken of as a copper-bearing district, there are many widely scattered occurrences of silver-lead ores, such as those of Milk Creek, Hudson Bay Mountains, Babine Mountains, and at points on Skeena River above Hazelton, also in Omenica. These places are far apart, and they indicate, at least, a very wide mineralization, and a large enough field for a great number of prospectors.

The copper deposits are of two main types, a large low grade chalcopyrite type in or about dykes, and a small fissure like type of bornite or chalcocite ore.

None of these are within, at present, a reasonable reach of transportation and very little is being done, or likely to be done, until the main-line of railway is built, and there is a further influx of population in the way of miners and prospectors.

Concerning the coal and mineral resources generally, and the geology of the Telkwa country, much information will be found in the summary reports of the Geological Survey for the last two or three years.—(Reports by W. W. Leach, and in the reports of Mr. Robertson, Prov. Mineralogist for British Columbia.)

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

ARTICLE III.

By F. W. Gray.

The Harbour Seam.

Next in importance to the Phalen Seam in the Glace Bay Basin ranks the Harbour Seam, so-called from the fact that it crops out in the shore of Glace Bay Harbour and was first worked there. It appears to have been one of the first seams to be mined after the General Mining Association relinquished their monopoly in 1858, and it seems to have been more extensively worked than the Phalen Seam for several years after this. Mr. Richard Brown in his "History of the Coal Fields of Cape Breton" states that the seam was opened in the spring of 1858 by Mr. Archbold, who drove levels in from the shore both at Glace Bay and Bridgeport and shipped the coal to vessels lying at anchor in the open Bay by means of scrows.

Previous to the formation of the Dominion Coal Company the most extensive workings on the Harbour Seam had been carried on by the Glace Bay Mining Company, who owned a small but strategically valuable area that took in the whole of the outcrop of the Hub Seam, a large portion of the Harbour Seam and the shores of Glace Bay Harbour, or rather what was then, as Mr. Brown describes it, "the long, narrow pond at the head of Little Glace Bay." The present harbour is almost altogether artificial. It was dredged out in the first instance by the Glace Bay Mining Company, who built the entrance piers, and are stated to have spent over $110,000 previous to 1886 in forming the present harbour, which, as the successors of the Glace Bay Mining Company, the Dominion Coal Company now own.

During the past few years the harbour has been still further improved by dredging, and new range lights and buoys have been provided by the Dominion Marine Department.

It is interesting to note that the amalgamation of the two companies working the Harbour Seam in the Glace Bay Basin, gave the present company some of their most valuable properties; namely, the key to the submarine coal field at Table Head and Glace Bay Harbour, the International Company's railway to Sydney and shipping facilities to Sydney Harbour

The seam averages about 5 feet 6 inches in thickness. It yields a hard coal having a high percentage of volatile matter and a comparatively small percentage of ash, which renders it especially suitable for gas-making purposes. Almost immediately above the coal there is a thick bed of sandstone with shale platings and numerous vertical joints. A certain amount of surface drainage percolates into the layers and flows down the vertical joints, for which reason the Harbour Seam is a little wet in the land area.

The Glace Bay Mining Company sunk a shaft near the shore of the Harbour about forty feet deep, and shipped their coal directly out of the mine car into vessels at the wharf. In 1876 two shafts were sunk about half a mile to the deep of the first shaft, reaching the Harbour Seam at 240 feet and known as the Stirling Shafts. The Harbour Seam was worked from these shafts until the property was taken over by the Dominion Coal Company, who closed the mine in 1895 and allowed it to fill with water The Stirling Yard is now used as a storage yard for lumber, equipment and general stores used by the Construction Department. During its life about 2,00,000 tons were extracted from the Stirling Mine.

The entire output of the seam from 1858 to the present time is eight and three-quarter million tons, of which quantity five and one-quarter million tons, or 60 per cent. of the whole, has been mined under the present management since 1893.

The two mines at the present time operating on the seam are International Colliery, now known as No. 8,

Glace Bay Harbor 20 years ago. Shows the old Caledonia Pier, and in the distance the Pier of the Glace Bay Mining Company, looking seaward. Photo loaned by Mr. C. H. Rigby.

Glace Bay Harbor 1908. Showing Schooner Loading Pier and Shores of P. E. Island, looking seaward.

and No. 9 Colliery which is worked to the same shaft as the Phalen Seam at No. 2.

Dominion No. 8 (International).

The International area was first opened up by shore levels in 1858, as previously mentioned. In 1863 the property was acquired by New York people, who formed the International Coal & Railway Company. This company constructed a railway from the mines to Sydney. The present structure of No. 1 International Pier at Sydney was built by the Dominion Coal Company on the original cribs of the pier first constructed by the International Coal & Railway Company.

Since its commencement the mine has put out 4,600,000 tons, of which quantity 2,800,000, or 57 per cent., has been produced since the property came into the hands of the Dominion Coal Company. The output at the present time is about 1,000 tons per day.

As is to be expected at such an old colliery, the equipment of No. 8 is not so large nor so modern as at the newer mines. The power consists of one 212 H.P. and one 318 H.P. Babcock & Wilcox boilers, and two old return tubular boilers of 75 H.P. each. The smoke-stack is of brick, 100 feet high and five feet in diameter. There is also a steel stack 70 feet by 3 feet 6 inches diameter. The old hoisting engine is the one originally put down, and is a 16″ x 32″ horizintal duplex reversible slide valve engine with a drum 8 feet 9 inches in diameter. The shaft, which is the one originally put down, is only 80 feet deep, and with the exception of the Emery Shaft it is the only one of the coal company's mines that has the ordinary rectangular English type of coal cage. The mine cars are run out of the cage at bankhead level, emptied at the screens and returned to the cage. At all the other shaft mines, the dumping cage and end-door mine, cars are used, and the cars do not leave the shaft. The workings are ventilated by an 8-foot fan.

The coal is cut entirely by hand and no machine mining whatever is done.

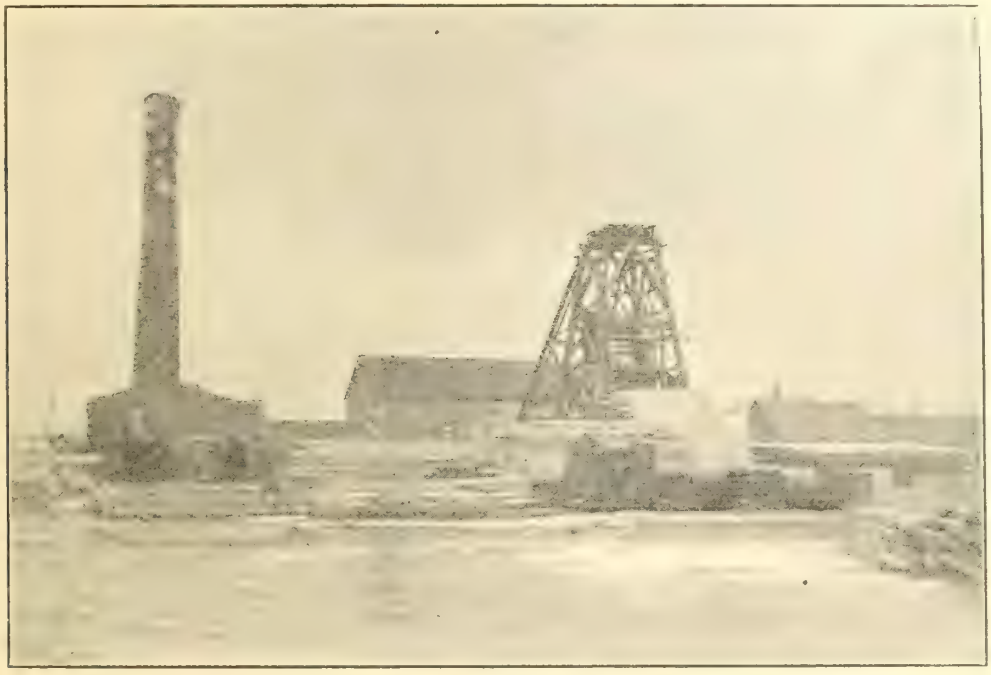
Although no gas is to be found in No. 8. Marsaut safety lamps are used as a precautionary measure, having been used since 1907. The mine employs about 400 men and has about 50 horses

Dominion No. 9.

The arrangements of this mine, exclusive of the underground workings, were described in conjunction with No. 2 Colliery. The territory at No. 9 is largely submarine, but except in this particular the seam differs in no way from that at No. 8. The accompanying plan will give an idea of the arrangements at the pit bottom, and shows the five compartments in the No. 2 shaft. The pit bottom is walled with concrete and supported by I beams, in the same way as the No. 2 pit bottom described previously. The coal is hoisted by the ordinary dumping cage, and is well sorted on picking belts.

For haulage purposes underground, three Porter compressed air locomotives are in use, of the following dimensions: 7 x 12 inches, 4 wheels, 7 tons; 7 x 14 inches, 4 wheels, 10 tons; 10½ x 14 inches, 4 wheels, 15 tons.

The coal is all machine cut. The output of the mine is from 35,000 to 40,000 tons per month. It employs about 550 men and has 60 horses.



Dominion No. 8 Colliery (International). Harbor Seam.

Pumping.

The water from International Colliery was formerly dealt with by steam pumps which discharged through boreholes at a point midway between the shaft of International Colliery and No. 2 Colliery and adjoining the line of the Sydney & Louisburg Railway. Two boilers were situated here and the steam was conveyed underground by a borehole. In 1906 it was decided to replace this plant by a water shaft and an electrically operated hoisting engine. A shaft was sunk 8 feet by 12 feet 6 inches, and was finished at the beginning of 1907. The coal was reached at a depth of 344 feet, but the shaft was continued to a depth of 370 feet for sumpage. The electric water hoist, which is operated by power from the Central Electric water hoist, which is operated by power from the Central Electric Plant at No. 2 Colliery, was made by the Allis Chalmers Bullock Co. It is driven by a 300 H.P. phase motor, 550 volts, 25 cycles, speed 720 revolutions per minute. There are two water tanks of 800 gallons capacity. The height of the lift is 340 feet; hoisting rope 1¼ inches diameter; hoisting drum 7 feet by 4 feet.

At Dominion No. 9 Colliery there has been, up to the present, a comparatively small quantity of water, but as the workings extend and the pillars are drawn the quantity of water will doubtless become larger, and it is proposed to install an adequate pumping plant very shortly.

The Old Stirling Mine. Yard now used as a Storage Depot for the Construction Department.

MINERAL VEINS IN THE MONTREAL RIVER DISTRICT.

In Volume II. of the Journal of the Canadian Mining Institute, which has just recently appeared are two papers on the above subject which are of especial interest at the present time, when an army of prospector is rushing northward from Cobalt into the Montreal River District and beyond, and active development work on an extensive scale is about to be undertaken on a large number of mining properties where native silver is known to occur.

One of these papers is by A. E. Barlow, and is entitled "The Origin of the Silver of James Township," and the other is by R. E. Hore, on "Cobalt-Silver Ores of Northern Ontario."

Unfortunately both papers are rather too technical in character and diction to be thoroughly enlightening to the ordinary prospector or miner. Nevertheless the following points are enunciated, namely: That the silver-bearing veins are closely associated with intrusive masses of quartz-diabase; and that these intrusives are in the form of laccoliths, injected more or less horizontally, into older rocks, though the former author seems to have forgotten this at times, or possibly there is some uncertainty in his mind on the point, for he speaks of the diabase in one place as a "batholitic mass," and in another place he refers to the "profound fissuring of the diabase," a phrase which could only be appropriately made in reference to a laccolith, if it were of very great thickness.

In addition to the above statements Dr. Barlow's conclusions are as follows:—

"The rock (diabase) is more highly quartzose than usual.

"The presence of the veins is due to a profound fissuring of the diabase itself, formed probably as a result of the contraction of the rock in cooling, the resultant cracks and cavities being occupied in many cases as fast as they were formed by the later, more acid and hydrated segregations from the same diabase.

"The veins in their simplest forms of development are, therefore, essentially of pegmatitic type, although some of the more complex types and those at the other extreme made up almost wholly of calcite or quartz show little or no evidence of such an origin.

The material of the veins is a diabase-pegmatite usually containing calcite.

In order of formation the principal gangue minerals are feldspar, calcite, quartz.

All the gangue minerals appear to have been derived from the surrounding diabase.

The native silver is not only present in association with these gangue minerals, but is common in the diabase forming the wall rock.

It is rather unfortunate that more exact descriptions of some of the veins are not given, for the impression that these statements leave in the minds of the readers is undoubtedly that the veins are more or less simple and homogeneous, being composed of pegmatite (locally known as "Aplite"), which grades off by decrease of feldspar into calcite and quartz. This, however, is quite different from the conditions which are found to prevail on the ground. When pegmatite is present the veins usually have a distinctly composite structure, one side being composed of pegmatite and the other of calcite, with a fairly sharp line of demarcation between them, although instances may possibly occur where this line is not well defined.

In Mr. Hore's article the principal conclusions drawn by him are as follows:—

"The diabase occurs in most cases in the form of large sills, a few hundred feet in thickness, lying nearly horizontal and parallel to the bedding of the Huronian sediments."

"The Cobalt ores have been deposited from solutions which followed the formation of veins of aplite (pegmatite) in the diabase. Owing to the fact that in the silver deposits in the district the silver minerals are intimately associated with cobalt minerals, the silver is believed to have the same origin."

It is also suggested "that the metallic sulphides and arsenides have been concentrated from the diabase magma by extreme differentation."

This last statement is distinctly at variance with the preceding one, which states that the ores were formed subsequent to the pegmatite, the last of the aqueous rocks now seen at the surface to consolidate from the fluid condition. With the exception of the presence of sheets of pegmatite occupying parts of the same fissures with them, the veins are similar to those in the diabase in the vicinity of Cobalt, which have been formed by deposition from aqueous solution. Evidence is entirely lacking to prove that the ores in them have separated out by any process of magmatic segregation from a fluid diabase magma. Any assumption that such is the case is, in my judgment, quite unwarranted.

There can be little doubt but that the fissures in which the silver-bearing veins occur have been caused, as in the Cobalt district itself, by the shrinking of the quartz-diabase or adjoining rock as it cooled and solidified, these fissures being usually normal to the general surface. In some cases they extended to the still molten interior or lower portion of the mass of the quartz-diabase, and allowed this liquid rock to rise up through them, and form narrow dikes.

Thus the dikes were formed after the surrounding diabase had solidified, but while it was still very hot.

As the diabase continued to cool and contract either the fissures in which the dikes of pegmatite had been formed were reopened, or altogether new fissures appeared, and then, and not till then, the mineralizing solutions invaded their fissures and deposited the ores with the calcite gangue, not only in the fissures themselves, but in minute crevices, both in the surrounding quartz-diabese and in the more brittle pegmatite.

It would be better not to speak of these pegmatite (aplite) dikes as "veins," as if they were definite parts of the gangue, the same as calcite and its associated minerals. Nevertheless, the pegmatite would appear to have a distinct significance in defining the positions of the most important fissures, and those which may reasonably be expected to persist to the greatest depths. Thus while it is not directly connected with the origin of the silver ores, any more than the surrounding quartz-diabase itself is so connected, it is an indication of the existence of fissures which extend to considerable depth, and in which ores are likely to be found in greatest quantities.

J. B. TYRRELL.

THE SHALE OIL INDUSTRY OF SCOTLAND.*

R. D. STEUART, F.I.C.

Nature of the Industry.

Shale is mined in much the same manner as coal, and after being broken into small pieces by machinery, is distilled in retorts and gives as products crude oil, ammonia water and fuel gas. The crude oil extracted from a ton of shale varies from 16 to 35 gallons, and the ammonium sulphate 30 to 70 pounds. The refined products of the crude oil are spirit or naptha 4 per cent., burning oil 33 per cent., gas oil 7 per cent., lubricating oil 20 per cent., solid paraffin 10 to 12 per cent.

The manufacture is allied to the great petroleum industry; only, instead of obtaining the crude oil by boring for it and applying pumps where necessary, as in the United States, Russia, and elsewhere, the shale has to be mined at much expense and retorted to procure the crude oil. The rapid and violent method of the retort gives a much coarser crude oil than the gentle age-taking processes of nature used in creating petroleum; so that besides the extra expense in producing the shale oil there is extra difficulty and expense in refining it. Petroleum often requires only one distillation as far as lamp oil is concerned, and after a slight treatment with sulphuric acid and soda it is ready for the market. The burning oil from shale requires three or four distillations and chemical treatments, and the proportions of chemicals required is heavy. One advantage that the repeated distillations give is the opportunity afforded for making better fractionated and more homogeneous products.

In a petroleum refinery the stills, being very large are few and there is not much plant to be seen, the tanks being often under ground. In a Scotch oilworks there are the great benches of shale retorts sometimes over 60 feet high, with the great stacks of numerous series of 3-inch pipes, 30 or 40 feet high for air condensers. There is the 3-story high sulphate of ammonia house, with its high column-stills, the acid saturators for the ammonia, vacuum or other evaporator for the sulphate from the recovered sulphuric acid of the refinery, centrifugal driers, storing bins, grinding mills etc. In the refining department the stills are small and, on account

*Reprinted with permission of Engineering.

of the repeated distillations, very numerous; the washers for vitriol and soda many; there are coolers, refrigerators, filter and hydraulic plate presses for the separation of the heavy oil and solid paraffin; great sweating houses for the paraffin refining; candle works; sulphuric acid making and concentrating; acid-recovery plant; engineers', joiners' and plumbers' shops, etc.—a very large and varied collection of apparatus covering much ground; so that for a comparatively small production there is a very large and expensive plant. A conspicuous feature of oilworks is the great hills of spent shale.

Extent of the Industry.

There are at present only paraffin oil works in Scotland. Three are smaller and produce only crude oil and ammonia. Four are larger and have fully equipped refineries. Two of them have candle works attached. Together they distil more than two and one-half million tons of shale in a year.

In 1906,

	Tons Shale.
West Lothian or Linlithgowshire produced..	1,791,896
Mid-Lothian or Edinburghshire produced....	732,635
Lanarkshire	21,051
Total	2,545,582

In 1906 the refined products were:

Spirit or naptha, sp. gr....680 to .750, about 2 1-2 millions imperial gallons.

Burning oils, sp. gr..... .790 to .830, about 17 millions imperial gallons.

	Tons.
Gas or intermediate oils, .850 to .870 ....about	38,000
Lubricating oils, .965 to .900 .....about	40,000
Solid paraffin wax, m. pts., 100° to 130° F..about	22,500
Sulphate of ammonia, over	50,000
Still coke, selling 60 to 70 shillings a ton	5,000

The total paid up capital of the four refining companies is about one and one-half million pounds sterling. The dividends last year were 5, 15, 15, and 50 per cent.; respectively; for this year 7, 15, 17.5 and 50 per cent.; but many years the dividend for most works was *nil*. The wages paid by the companies are about £700,000 a year. There are 8,300 men employed, including 3,380 miners.

The whole industry is small in comparison with the mineral oil requirements of the country, nevertheless it is large enough to cause the light of the common people to be supplied at less than one-half the price that would have had to be paid if dependent on foreign kerosene only.

Origin of the Industry.

James Young (born 1811) started life assisting his father as a cabinet-maker in Glasgow. He attended lectures on chemistry given by the great Professor Thomas Graham, showed aptitude, and became Graham's assistant for seven years. He followed Graham to London when he was appointed to the professorship at University College. By and by Young became manager for four and one-half years in Muspratt's chemical works, near Liverpool. He afterwards held an appointment for many years in Tennant's chemical works, Manchester. While there he was written to by Professor Lyon Playfair (afterwards Sir Lyon and Lord Playfair) telling him of a spring of petroleum in a coal pit at Alfreton, Derbyshire, which he suggested Young should erect works to refine. Young did so, starting, I suppose, the first petroleum works of present day type. The crude oil was of the consistency of thin treacle, and the quantity about 300 imperial gallons a day; and from it was manufactured illuminating and lubricating oils. Solid paraffin in small quantity was extracted and made into candles. This was in 1848. Within two years the oil began to fail. The mode of its occurrence had suggested to Mr. Young that it had been extracted from the coal by a subterranean low-temperature distillation, and he set himself to make a similar oil artificially. He tried many coals of England and Scotland until he discovered the Torbanehill or Boghead gas coal (see p. 584). This substance gave him the products he wanted. He took out patents for the low-temperature distillation of coal both in Britain and the United States; and in partnership with Mr. Meldrum, who had managed for him at Alfreton, and with Mr. E. W. Binney, of Manchester, the geologist, who supplied the capital, works at Bathgate were started in 1850. During the next ten years works were erected at various places in the United States to distil coal or shale by this method, some with license from Young, and his method of refining by fractional distillation from stills and treatments with sulphuric acid and with soda well known; so that when after 1859 petroleum became plentiful, the method was familiar, and works suitable for its refining were already in existence and at hand. During those years great interest in bitumens and bituminous minerals was being taken in America and all over the world, and many investigators were in the field, and modern works and methods could not have been long delayed, nevertheless James Young stimulated thought in Aemrica, introduced suitable petroleum lamps, and helped at once to give things a right direction; and he has some claim to be considered the father not only of the Scottish paraffin oil manufacture but also of the great petroleum industry of America.

James Young amassed a fortune, which his genius and enterprise deserved; bought estates in several parts of Scotland, among others, Kelly in Renfrewshire on the Frith of Clyde. He recived the honorary degree of LL.D. from St. Andrews University, was an original member of the Chemical Society, and F.R.S. of London. He died in May, 1883. He invented the method of making chlorate of potash, etc. He was a great friend of David Livingstone, the African traveler, who laid the foundation stone of Addiewell works for Dr. Young.

The Minerals Used.

The Torbanehill mineral was used about twelve years in Scotland for paraffin oil manufacture. Some was exported to the continent of Europe and to America for the same purpose. After that time it soon became exhausted. Shale was started early in the sixties and has continued ever since. Gas and parrot coals were also used. Throughout the Coal Measures there were many bands of shale, and often in connection with coal seams. Above the coal seam there was often a thin bed of shale, and under the coal a thin bed of black-band ironstone. Shale seams were worked in the Clyde valley coal fields in connection with the Splint and Virtuewell coals, the mussel-band ironstone, and the Kiltongue coal. In Fife, Midlothian, Lanarkshire, Stirlingshire, Renfrewshire and Ayrshire, shale and bastard parrot coals were worked in the Coal Measures, Millstone Grit, and Mountain Limestone. In the early and bright days of the industry shale or gas coal was worked for oil at various places in the English coal fields also, for instance, in Yorkshire, Cheshire, Lancashire, Staffordshire, and especially Flintshire in North Wales. In Flint the Lees-

wood cannel seam was from fix to six feet thick, of a limited basin-shaped area, and it thinned at the edge: All have been stopped for many years. When American petroleum was imported in large quantity the prices of products fell, the richer cannel coals were used for gas making, and the bastard paraot coals and shales of the Coal Measure, both in England and Scotland ceased to be mined; so that for many years now the manufacture has been confined to the shales of the calciferous sandstone (see p. 587).

Locality of the Industry.

The locality of the industry may be appreciated from the map, Fig. 53.

The middle of the shale fields lies thirteen miles due west of Edinburgh. It is a strip of country five to eight miles wide, stretching from the shores of the Firth of Forth north of this point southward for sixteen miles. It passes through the counties of West Lothian and Mid Lothian and ends within the borders of Lanarkshire, near the western termination of the Pentland Hills. It contains the shale-working districts of Dalmeny, Philpstoun, Winchburgh, Uphall, Broxham, Mid-Calder, West Calder and Tarbrax. The accompanying map shows the

FIG. 53. Map of the south of Scotland, with calciferous sandstone shown darkened and the shale field black.

location of the district and also of the areas of the calciferous. Oil shale beds are found, although not at present worked, in a narrower strip farther east, and not long ago there was an oil work on it near the village of Pentland. A limited continuation of this band is found beyond the Forth in Fife at Burntisland and here also an oil works was in operation fifteen years ago or so. These districts may yield some oil shale in the future. The accompanying section, Fig. 62, page 594, shows the structure of the West Calder shale field. A series of columnar sections at different points is given in Fig. 54, page 579.

History.

The first oil work starting in 1850, there were about 6 in 1860, 90 in 1870, 26 in 1880, 14 in 1890, 9 in 1900, 7 in 1908.

The first government statistics of shale were taken in 1873, 23 years after the start of the manufacture. We give the annual output in Scotland, and, for the sake of space, selecting only every tenth year, for comparison.

1873	524,095	tons shale
1883	1,130,729	tons shale
1893	1,947,842	tons shale
1903	2,009,265	tons shale

Although the number of works was reduced the total production was kept up.

Soon after 1860 American petroleum was imported in large and increasing quantities. At first only lamp oil was imported and the Scots modified their retorts and heats to get a larger proportion of the heavier products. They bought petroleum residuum from America to refine into lubricating oils. Soon the Americans took up the refining of heavy oils for themselves and flooded Britain with it also, and the Scots improved their freezing plant to get more solid paraffin. Soon also solid paraffin was imported in large quantities, and now the retorts were lengthened and suited for increasing the production of sulphate of ammonia. Peruvian guano had long been used by the British farmer as an important source of combined nitrogen. By 1880 it began to become exhausted and the price of sulphate of ammonia rose as high as £24 a ton. This put new life into the industry followed by over-production; also the increased import

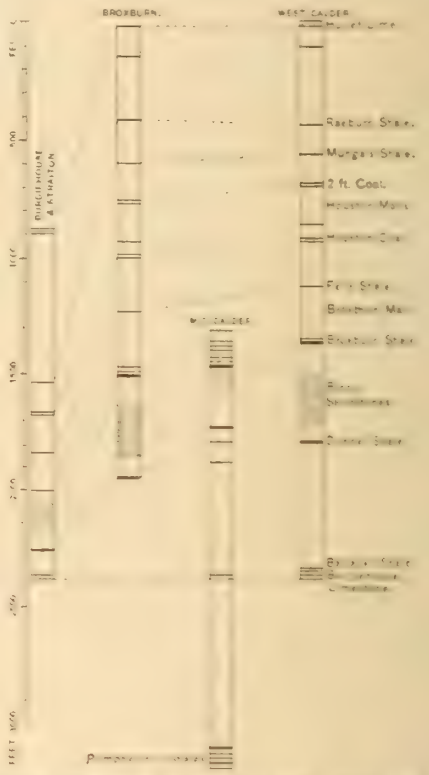


FIG. 54. General section of the West Calder shale field and carboniferous limestone series to the west. (After H. M. Caddel, *Geology of the Oil Shale Fields of the Lothians.*)

of nitrate of soda had by 1890 lowered in large quantities by iron works, coke ovens, Mond gas producers, etc., besides combined nitrogen being made from the atmosphere by electrical means, and although America has harnessed Niagara for that purpose, nevertheless, on account of the increasing demands for nitrogenous fertilizers the price of sulphate has for some years kept up to £12 a ton. There has been keen competition also in later years with petroleum products from Russion and Roumania, and solid paraffin from Galicia. The Scottish industry still manages to exist and some companies to pay a handsome dividend. The price of burning oil during the fourteen years of Young's patent was about two shillings and sixpence a gallon; for many years now the price has been about sixpence.

This history of this war of competition records many defeats, many casualties. Every new move of the competitors swept many oil works out of existence. Every

new step forward in retorting or refining would bring a temporary hopefulness and new works would start, soon again to be stopped. During the 57 years of the existence of the industry 120 different works have been thus started and stopped, some without ever paying a dividend. Much capital has thus been permanently lost. The companies that have kept in existence have succeeded in doing so by improving methods and plant, but principally by increase of size enabling them to cheapen production by concentration.

Retorting and Refining.

There has been great variety in the form of retort and of condenser tried by the numerous works. The first retort used by James Young was a horizontal one of cast iron, of the shape and size then used for gas-making (see Fig. 55). Horizontal retorts were used by others in many sizes and shapes; but Young very soon adopted a small vertical retort of circular section, which was luted into a water trough below, from which the spent shale was drawn in small quantity every hour (see Fig. 56). By and by it was fitted with a bell hopper on top, which was charged every hour, alternately with the drawing every half hour. Soon also steam was injected at the bottom and found to be a great improvement both for quantity and quality of the crude oil. Several retorts were heated by one coal fire and, being dependent on the care of men, they were often over-

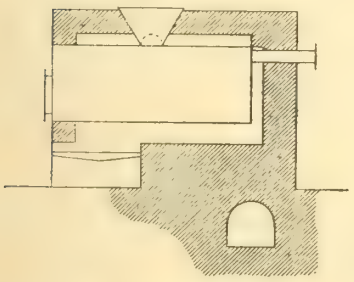

FIG. 55. Horizontal retort.

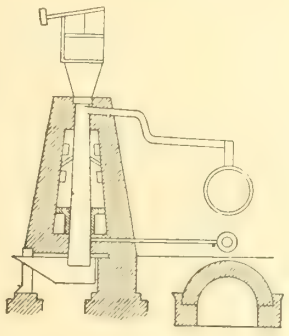

FIG. 56 Old vertical retort.

heated, which spoiled the crude oil and destroyed the retort. The distillation was upwards. The steam helped to diffuse the heat through the mass of shale and to sweep the oil vapors rapidly out of the heat, where the valuable solid paraffin and heavy oil tend to deposit carbon and become decomposed into lighter products. The vertical retorts were increased in size, and oval and other forms were adopted. Some were tried with internal combustion and limited inlet of air but were not successful. William Young tried a double casing, ensuring the gentle heat best for a good crude oil, producing heavy products, solid paraffin and decreased loss in refining. It showed how much could be done in improving the crude oil, but otherwise was a failure.

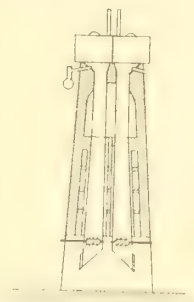
In 1873 N. M. Henderson invented a retort which, besides giving with precision the gentle heat wanted, also used the spent shale as fuel and thereby reduced the cost of manufacture. Four retorts were erected in one oven over the one furnace; and the spent shale, with its 12 per cent. of fixed carbon, was dropped from each in succession at four-hour intervals and supplied with a limited amount of air; each retort being emptied and recharged every sixteen hours. Steam was superheated in pipes placed in the retort ovens, and the incondensable gases of the distillation were burned in the oven. The very best crude oil was made by this retort, and the ammonia was also slightly increased.

The modern type of retort was the invention of Geo. T. Beilby and and William Young, in 1881. By it the ammonia was doubled or more, and much fuel gas was produced. Four metal retorts were connected with a large hopper above (see Fig. 57) common to the four. The distillation was upwards through the cold shale of the hopper where the crude oil was condensed and redistilled. Each retort had an iron upper part where the oil was distilled from the shale at a low temperature.

FIG. 57. Young and Beilby retort.

The shale was passed down through the lower part made of firebrick, where it was subjected to as high a temperature as possible without fusing, and acted on by steam. The nitrogen was partly converted into ammonia, and the carbon into producer gas. At intervals in the bench of retorts there was one for coal to act as a gas producer to supplement the retort gas, and the ammonia from it was also saved.

The retorts now in operation are on the Young and Beilby principle. I may mention as examples the Bryson retort (see Fig. 58) and the Henderson retort (see Fig. 59). The Bryson is of circular cross-section, the Henderson oblong. Both are continuous working. In the Bryson there is a table below to support the column of shale, with a revolving arm to take the spent shale from the table and keep up the slow movement downwards. In the Henderson the same result is brought about by the slow motion of two toothed drums. Henderson increased the length greatly, and, with an ordinary shalefi the retort makes more gas than it requires for its own use. From ground level to top of hopper is 63 feet, and 15 tons of shale are in a retort at a time. The metal part of retort is 14 feet long and 2 feet 9 inches by 1 foot 3 inches at the top. The brick part is 20 feet long and 4 feet 8 inches by 1 foot 10 inches at bottom. The throughput per day is four to four and one-half tons of shale.



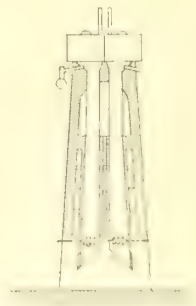


FIG. 58 Bryson retort

The distillation of the ammonia water is much the same as in large gas works. A large works may turn out thirty tons of sulphate of ammonia per day.

The refining consists of distillations and treatments. The distillations separate the various products from each other by boiling at different temperatures; and the continuous-working, connected-still system of N M. Hen-

derson is in general use. The chemicals used in the treatments are oil of vitriol which separates a black tar, and caustic soda which also separates a black tar. Distillations and treatments are repeated several times. The amount of oil of vitriol used is about three to four per cent. by volume on the crude oil.

The heavier oils are first cooled naturally and further by freezing machine, and the solid paraffin separated by filter presses, and, generally, further pressed by hydraulic machinery. Both types of ammonia freezing machine are in use, viz., condensed gas and solution. The solid paraffin is refined by sweating, and Henderson's patented method is in use in all the refineries. A little is refined by naptha pressure. A treatment with cyanide char and filtering through paper is the finishing process.

The cost of mining of the shale varies very much according to the circumstances from 3 to 6 s. per ton. The retorting of the shale costs 1/6 to 2/ per ton. The refining of the crude oil costs ¾ d. per gallon of crude oil. The lordship charged by the proprietor of the soil is 3 d. to 10 d. per ton of shale. The stirring tanks for the chemicals do not attain the magnificent sizes of the American refineries, the largest being about 40,000 gallons.

Geology.

The Torbanehill or Boghead Mineral.

This was the first mineral used by Young, Meldrum, and Bingey. It was found in a small basin a little to the southwest of Bathgate, two or three miles in diameter; and nowhere else in the United Kingdom.

It may be described as consisting of 20 to 30 per cent. of clay mixed with 70 to 80 per cent. of carbonaceous matter. This is insoluble in benzene, turpentine, carbon bisulphide or petroleum spirit, and is therefore not of the nature of petroleum or bitumen, although it gives petroleumlike products by destructive distillation at 700° or 800° F. The mass of carbonaceous matter seems without structure, and the fossils were found throughout the bed and not merely on the surfaces of seams, as is general with coal. It contained impressions of *Sigillaria* and *Stigmaria,* and the few inches of fire clay below it contained *Stigmaria,* the *Sigillaria* sometimes proceeding upwards through the torbanite in its natural position when living. There are no fish remains, although these are generally found in Scotch cannel coals. The microscope sometimes showed the scalariform tissue of tree ferns, also the spores of ferns in clusters. Torbanite is no doubt the remains of organic matter in its original position and not a product of distillation, as some have suggested; a distillate would have been soluble in petroleum spirit. Renault considers both torbanite and oil shale to be mainly alteration products of masses of gelatinous fresh-water algae from which oxygen has been eliminated, and containing immense numbers of bacteria, especially micrococri. In cannel coals the prevailing vegetable constituents are spores of cryptogamic plants, algae being rare and in many cases absent.

The Torbanehill mineral is of a brown or nearly black color; there were brown and black varieties, and the brown was the richer. It had a yellow or fawn-colored streak without lustre, and subconchoidal fracture, was amorphous, and apparently homogeneous when fresh, but showed distinct stratification when spent in the retort. It was very indestructible and did not deteriorate with weathering. Near basalt dykes it became soft, sticky, and brown, resembling melted india-rubber. In the laboratory it takes fire readily when put to a flame, splits, does not fuse, burns with a very smoky flame, giving an empyreumatic odor, and leaving a considerable amount of white ash.

The crude oil taken from it was 90 to 130 gallons per ton; sp. gr. about .890. It was richer in the east part of the field than the west, and it deteriorated somewhat with depth. It yielded 44 to 48 per cent. of crude oil and 1 to 1½ per cent. of solid paraffin. It has been analyzed by many chemists.

Heated in a close crucible the mineral gave (Dr. Fyfe):

> 67 to 70 per cent. volatile hydrocarbons, 6.6 to 16.3 per cent. fixed carbon, and 12.8 to 23.2 per cent. ash.

The following analysis is by Anderson:

Carbon	64.02
Hydrogen	8.90
Nitrogen	0.55
Sulphur	0.50
Oxygen	5.66
Ash	20.32
Total	99.95
Ash: Silica	56.09
Alumina	40.04
Peroxide of iron	3.24
Lime	0.34
Magnesia	0.46
Total	100.17

The sp. gr. varied from 1.17 to 1.316.

It differs from coal in having a larger proportion of hydrogen and in not leaving a coke on distillation. In ordinary gas coal the proportion of carbon to hydrogen is 100 to 10; with Torbanehill mineral 100 to 14. The geological position was near the base of the coal measures overlying the Millstone Grit.

The seam varies from one inch to thirty inches in thickness. There were vertical joints that cut it into irregular cubes. In a pit at Torbane the section was as follows:

	Feet	Inches
Boghead house-coal	2	7
Arenaceous shale	6	0
Shaly sandstone	0	7
Shale and ironstone containing remains of plants and shells	0	10
Cement stone (impure limestone)	0	4
Boghead cannel	1	9
Fireclay full of stigmariae	0	3

Then came six inches of common coal, and a series of thin seams, one inch or less of black shale, coal, shale, coal, fire clay, etc. The roof above the cement stone contained remains of calamities; the iron nodules, fossil shells of genus *Unio* (E. W. Binney).

The Oil Shale.

Good typical shale is of black or brownish color, fine in the grain and free from grit. It is distinguished by its brown streak, and its resistance to disintegration by weathering. It is tough and sometimes flexible. Under the knife the thin shavings turn up and curl over. Poor shale or "blaes" is friable under the same test and exposed to the weather soon breaks up into small fragments, and before long crumbles into clay. The richer

shales are nearly black but they are found in all gradations of color through brown to gray, as they decrease in quality. They are made up of fine laminae which become apparent when exhausted of organic matter by distillation. Some shale is "plain," that is, the laminae are parallel with the stratification of the seam. Other shale is "curly," and the layers, as if by side pressure, are crushed into wave-shaped, curled, irregular masses, with black brightly polished surfaces. There are often plain and curly layers in the one seam, one layer having remained rigid while the other slid and folded itself in the places of reduced pressure.

Although generally called bituminous shale, it is free from bitumen, having practically nothing soluble in ether or petroleum spirit. The carbonaceous matter present is also different from coal. Ordinary coals, by low-temperature distillation, give about 25 to 30 gallons per ton of liquid distillate, which is not a crude oil but a coal-tar, and has a specific gravity of over 1.00; and sulphate of ammonia about 20 lbs. to the ton. The high-specific gravity of the tar arises from the large proportion of ringed compounds of the benzene type, etc. In the crude oil of shale the specific gravity is .860 to .880 generally, and itis largely composed of the paraffin or chain series of compounds. There are many shales in the shale measures. The higher ones give a larger yield of crude oil, of higher specific gravity, larger loss in refining and less solid paraffin, and less ammonia. The shales and bastard parrot coals that used to be worked in the higher stratigraphical levels of the coal measures, had still higher specific gravity as of more of the nature of coal, with sp. gr. up to .930 or even .950.

Broxburn seam shale, which may be taken as an example, by ignition in a closed crucible, gave

	Per Cent.
Volatile matter	25.5
Fixed matter	74.5

In the fixed matter 4.95 was carbon, and 69.55 per cent. ash. The ultimate composition of Broxburn seam shale, dried, was

	Per Cent.
Carbon	19.12
Hydrogen	2.94
Nitrogen	0.54

Mills gives the composition of the ash of good average shale as

Soluble in water (containing SO_3 0.92 per cent.)	8.27
Silica	55.60
Ferric oxide	12.23
Alumina	22.14
Lime	1.55
Magnesia	trace
Sulphur	0.94
Total	100.73

Total sulphur in the shale 1.80 per cent. Total sulphur in the ash 1.31 per cent.

Shales from other parts of the world may be rich in oil although coarse-grained, gritty, and not curling under the knife.

As an example of shale from the coal measures, the Leeswood seam of Flintshire may be given. Five to six feet were worked.

Upper portion, smooth cannel 25 to 30 inches thick, gave 16 per cent. of crude oil of .925 to .940 sp. gr.

Then curly cannel, 18 inches, giving 30 per cent. crude oil; sp. gr. .875 to .890.

Then shale or bastard cannel 14 to 24 inches, 12 to 15 per cent. crude oil; sp. gr. .900. In some places this shale was replaced by common bituminous coal, and adhering to the cannel above gave a distillate containing the benzene and naphthalene series of compounds as in coal-tar, and spoiled the burning of the lamp oil.

The calciferous sandstone series of the Lothians contains over twenty different seams that have been or are capable of being worked. The ones lying on the higher stratigraphical level may yield as much as 45 gallons crude oil to the ton, the lower ones less, the lowest about 16 gallons. With ammonia it is the reverse, the upper ones least, 20 pounds or so, the lower ones most, 50 to 70 lbs. to the ton. The gradual change in the nature of the seams as they get deeper may partly arise from the greater age of the deeper ones, combined with the higher temeperature to which they have been subjected. There are many seams of igneous rock intruded among the

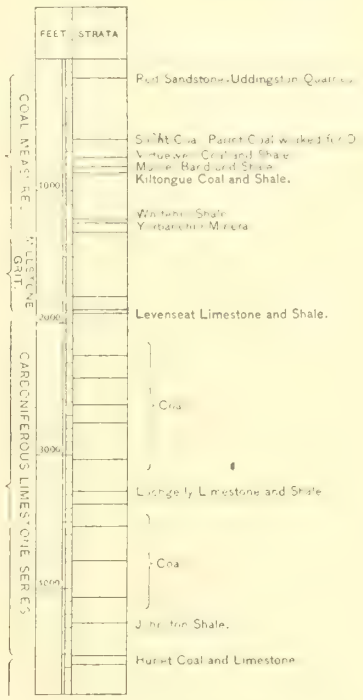

FIG. 60. Generalized columnar section of the shale fields of Mid and West Lothian.

shales, and the heat of these would help to cook the deeper ones to gentle decomposition; for what we have in the shales is the residue of a gentle, age-taking decomposition of organic matter giving results something like destructive distillation. The resulting gases have sometimes escaped; but with an impervious roof they accumulated under pressure and escape when a bore is sunk into the strata. Shale subjected to heat in a covered vessel at about 600° F. or 300° C. distills off almost all the carbon and hydrogen but leaves behind 63 per cent. of the nitrogen (Beilby). Coal at 300° C. in a closed vessel loses a considerable weight but none at all of the nitrogen (Carrick Anderson). So that age, along with the increased but still mild temperature of the greater depths, goes a long way to account for the decreased yield of crude oil but increased yield of ammonia for the deeper shales. The higher shales tend to give a crude oil of higher specific gravity than the lower ones, with less solid paraffin, and this partly arises from age and heat also; but not altogether. Sometimes within a

few feet of each other, as in the Leeswood shale before mentioned, there are seams, one of which gives a high, the other a low, gravity of crude oil, from a difference in the original materials deposited—a difference in the proportion of coal-giving materials. A seam of shale, good near the outcrop, often deteriorates as to quantity of oil as it dips deeper under superincumbent strata.

Entomostraca are common in many shales together with fish and plant remains. Animal matter may sometimes add to the proportion of ammonia extracted from shale.

The Calciferous Sandstone.

This is the lowest division of the carboniferous system. Its distribution is shown on the map, Fig. 53, It comes under the Carboniferous Limestone and rests comfortably on the upper Old Red Sandstone. There is a triangle of this formation in the Lothians bounded on the north by the Frith of Forth, on the west by the Bathgate Hills, and on the southeast by the Pentland range of hills. An anticlinal fold or arch coincides with the general line of the Pentlands, and the Lower Old Red Sandstone and Upper Silurian are brought to the surface. Denudation has removed all the carboniferous rocks from the Pentland Hills just as in the calciferous sandstone district all the higher divisions of the carboniferous system have also been ground off. The country north of the Pentlands would have been reduced to an approximately level plain had it not been diversified by masses of intrusive igenous rock which here and there have produced little hills with the ordinary crag and tail form due to glacial erosion, the crag towards the west and tail towards the east. These relations are illustrated in the section, Fig. 62.

The calciferous sandstone of Scotland consists of two subdivisions: (1) A lower one, the cement stone series or Ballagan beds, varying in thickness from less than a hundred to several thousand feet, made up of alternations of thin clayey limestone or cement stone bands, thin micaceous sandstones, shales and mud stones, but no oil shales. They are evidently lagoon deposits. These crop out towards the east, and a large part of Edinburgh is built upon them. (2) A higher one, the oil shale series, over 3,000 feet thick, which contains the many good shales, and crops out toward the west and forms the good shale country already mentioned, stretching from the Frith of Forth to the southwest end of the Pentlands. There are in it white, red and yellow sandstones, blue, gray, green and red marls or clays, blue and black shales, thin coals, fire-clays and estuarine limestones. The sandstones are of great importance for building stone, a considerable proportion of Edinburgh and other towns being built from them. The limestones also are of great economic importance, and besides serving for mortar and for agricultural purposes, have supplied vast quantities of limestone for the iron furnaces of the west of Scotland. The seams of limestone afford great assistance in defining the positions. The richest oil seams of shale lie between the Hurlet limestone which is the upper limit of the oil shale sub-formation, and the Burdiehouse limestone which for long was considered the lower limit; but 800 feet below this position the Pumpherston shales occur. Both Hurlet and Burdiehouse are well known and easily recognized; and certain thin seams of limestone, although of little value economically, are so persistent over the field that they are good guides to the borer in determining his exact position.

One significant feature of the district in connection with the history of the oil shales is the abundant development of igneous rocks. There are beds of volcanic tuff lying interstratified with the sedimentary strata over considerable areas and in definite positions. There are volcanic necks in seven or eight localities; and sheets of dolorite that cover great areas, one in particular. It has preferred to intrude itself into the position of some good shale or other, not always keeping to the same horizon, however, and at some places itself splitting into several distinct sheets. Over a large area this sheet will only average a few feet, but at certain places it swells out in laccolitic fashion to 80 feet or more. These sheets have generally been intruded when the sediments were

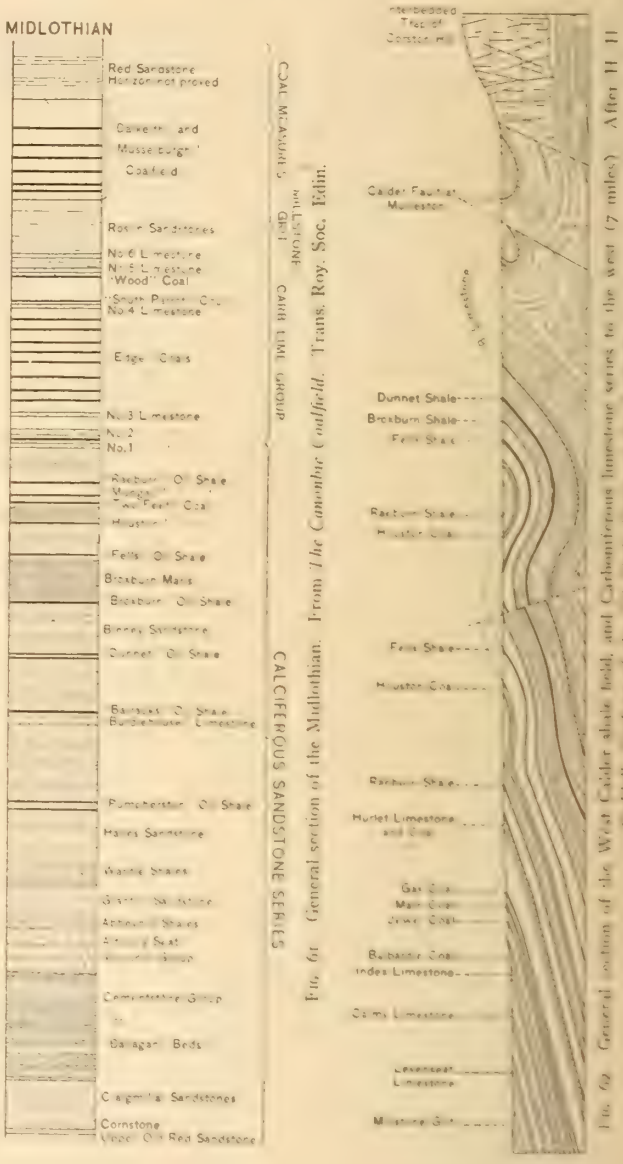

Fig. 61. General section of the Midlothian. From *The Carboniferous Coalfield*. Trans. Roy. Soc. Edin.

Fig. 62. General section of the West Calder shale field, and Carboniferous limestone series to the west (7 miles). After H. H. Cadell, *Geology of the Oil Shale Fields of the Lothians*

comparatively level. Since then the strata and sill together have been wrinkled into great waves, a succession of synclines and anticlines, and these have a general trend north and south. There are four great faults across the shale field with the same general direction—east to west at first and sweeping down to southwest or south. The displacement is often 1,000 feet, sometimes nearly 2,000 feet. The down-throw is to the north except in the most northerly. There are many smaller faults and many branches to these. At one place a dyke of igneous rock 100 feet wide has destroyed the shale for 70 feet on each side of it. There was no gas in the

burned shale; but on mining a road through the basalt dyke it was found to be itself charged with inflammable gas under considerable pressure. There was also a spring of brine. The distillation products had been permanent gas. Where, in another place, the sill 5 feet or so thick had taken the place of a shale and destroyed it, there were cavities in the sill partly filled with a yellowish semi-solid hydrocarbon, something like vaseline, and the cavities were lined with crystals of calcite, or, rarely, with barite. The hydrocarbon had the composition, carbon 84.35 per cent., hydrogen 12.83 per cent., nitrogen 1.68 per cent., trace of sulphur (R. Tervet). No doubt the hydrocarbon was the product of distillation of the shale and the temperature of the sill had not been high enough to convert all permanent gas. There was no outlet for the vapors and they had to make room for themselves in the molten trap. Another good seam of shale lying only 8 feet below the sill was not in the least harmed; another proof of comparatively low temperature. The strata at the time would probably be under water and water-logged, which would help to keep down the temperature, and also shut in the vapors. Often the shale comes close to the igneous rock and is quite good until it practically touches. Sometimes, however, the temperature has been destroyed for a good many fathoms both above and below.

The calciferous sandstone towards the west dips under the coal measures. When it rises again to the surface farther west at the other side of the coal basin, there is no sign of shale. It dips also under the edge coal to the east, and when it comes to the surface again beyond the coal field the shales have either disappeared entirely or become so attenuated as to be not worth working. The calciferous sandstone covers a large area in other parts of Scotlandd; but altogether without oil shale, or with a mere suggestion. So the circumstances suitable for deposits of oil shale seem to have been confined to this limited locality.

The strata of the oil shale field being wrinkled into numerous waves as described, the result of the folding and also of the faulting is to bring again and again the same seams to within working distance of the surface over a considerable area. Instead of having one clean strike north and south the outcrop of the shales forms a wide-stretching network. In searching for shale in a new locality many bores have to be put down, and trial pits, to make certain the shale is sufficiently extensive to be worth the expense of a mine or pit shaft, otherwise faults or intrusive whin may render the whole undertaking fruitless. There is boulder clay over most of the field, sometimes more than 200 feet deep, and this conceals theh indications that might be expected on the surface; and often there is little information to be gleaned from stream sections.

Boring to 100 fathoms costs about £300, to 200 fathoms about £800 or £1,000. Sinking a mine costs £15 to £30 a fathom. These all vary much at different times and according to the circumstances.

General Section of the Shale Districts.

The Hurlet limestone and coal is the upper limit of the shale subformation.

Strata. 450 ft. at West Calder, 400 ft. at Broxburn, etc., consisting of blaes, ironstone ribs, black-band ironstone, pebbly sandstone, etc.

Raeburn Shale. 3 to 6 ft. thick, giving 40 to 55 gallons of crude oil to the ton and 14 lbs. sulphate of ammonia. Worked in limited areas towards the southwest. In the south Cobbinshaw field there is another shale about 100 ft. above the Raeburn.

Strata. 140 ft. at West Calder, 190 ft. at Broxburn; blaes fire-clay, sandy blaes, ironstone bands, etc.

Mungle Shale. 2 ft. 35 gallons crude oil, and 30 lbs. sulphate of ammonia. Not much worked.

Strata. 130 to 190 ft.; chiefly blaes with fire-clay and iron-stone bands.

Two-feet Coal. 1 to 3 ft. Varies from cannel coal in one district to smithy coal in another. Worked a little at one time at Broxburn along with a thin shale and an ironstone. Immediately above the two-feet coal in some districts are interbedded volcanic tuffs.

Strata. Houston Marls. 230 ft. They are green or reddish, massive, amorphous, mudstone-like beds, hard when fresh but crumble down when exposed. I nbeds of a yard or two in thickness separated by thin bands of a harder and more permanent nature; homogeneous and structureless within the limits of the bed. Unfossiliferous. It has been suggested as accumulation of volcanic dust, but it contains much less silica than the most basic of volcanic rocks. Silica 35 to 40 per cent., ferrous oxide about 3 per cent., ferric oxide 6 per cent., alumina 20 to 22 per cent., lime about 11 per cent., carbonic acid 11 per cent., etc., deposited in water during a long cessation of oil-shale-making conditions.

Gray Shale of Addiwell. Less than 2 ft. generally. Not much worked. Composed largely of entomostraca, "squeezed together like grains of linseed in oil-cake."

Strata. 60 ft.; blaes, fire-clay, etc.

Houston Coal. 4 to 6 ft. The lowest coal that has been worked to any great extent in Scotland. It lies 2,000 ft. lower than the lowest workable seam of the carboniferous limestone. It is an inferior coal, pyritous, and with blaes interbedded. It had been much worked at the outcrops in very early times, but is not worked now.

Strata. 150 to 250 ft. thick. The principal shale of the West Calder district Extensively worked all over the shade district. 26 to 40 gallons crude oil and 20 to 35 lbs. sulphate of ammonia.

Strata 150 to 250 ft. thick. Extensively worked all over the shale district. 26 to 40 gallons crude oil and 20 to 35 lbs. sulphate of ammonia.

Strat. Broxburn Marl. 135 to 270 rt. Imemediately under the Fell's shale there is limestone 3 to 5 ft. thick, that the borer looks for as proof that the shale is Fell's . Then come greenish, marly or ashy clays with very hard cement stone from 1 inch to a yard in thickness Therè are no sandstones.

At Oakbank 12 ft. above the Broxburn seam there is—

The Big Shale, 4½ ft., 22 gallons, and 13 feet higher still
The Wee Shale, 1½ ft., 36 gallons. These are generally wanting elsewhere.

Broxburn Shale. This has always been an inferior shale in the West Calder district, 4 to 6 ft.; but it is the principal shale at Broxburn, Oakbank and other localities. At Broxburn there are three seams:

The Broxburn Gray, about 6 ft., 23 gallons 35 lbs.

The Broxburn Curly, 5½ ft., 26 gallons, 38 lbs.

The Broxburn, 5 to 6 ft., 28 to 35 gallons, 40 lbs.

At Oakbank, where these three seame are found along with the two extra ones above, 16 ft. under the Broxburn seam there is another shale of 4 ft.. the Wild Shale.

Strata. 400 to 500 ft.; blaes and marl on top and then the Binny Sandstone, thick massive beds which have been extensively worked for building stone throughout the district. Blaes and marl below.

Dunnet Shale. 4 to 12 ft. 24 to 333 gallons crude oil and 24 lbs. sulphate of ammonia. The principal shale at Pentland, Duddingstone and Burntisland, and extensively worked in other districts.

Strata, 400 to 600 ft. Sandstone, blaes, and limeribs, 10 fathoms below the Dunnet seam at Broxburn there is a stratum saturated with petroleum and brine.

Barracks Shale. Sometimes 8 ft. thick and yielding 22 gallons per ton, but generally thinner and poorer in oil.

Strata. 40 ft. blaes. Sometimes only 5 ft.

Burdiehouse limestone. Soemtimes as much as 64 ft. thick and both quarried and mined. Extensively worked throughout the region. Burned for local use for building and other purposes, and sent off in great quantities to the iron works of the west of Scotland. A fresh-water or estuarine limestone, with numerous fossil fishes, and distinguished by the abundant remains of a small ostracod crustacean *Leperditia Okeni* var. *Scotoburdigalensis*. It often rests upon a characteristic pavement called the "Buckie fake," containing the small gasteropod *Platyostomella Scotoburdigalensis*. Some places this limestone is only 10 ft. thick or less.

Strata. 678 ft. at Broxburn. Blaes with thick sandstones in the centre.

Pumpherston Shales.

No. 1, or Jubilee Seam. 8 ft. 18 gallons crude oil, 55 sulphate of ammonia.
Strata Blaes, 14 ft.
No. 2, or Maybrick Seam. 5 ft. 16 gallons crue oil, 60 lbs. sulphate of ammonia.
Strata. Blaes and ribs, 13 ft.
No. 3, or Curly Seam. 6 ft. 20 gallons crue oil, 60 lbs. sulphate of ammonia.
Strata. Fakes, blaes, 12 ft.
No. 4, or Plain Seam. 7 ft. 20 gallons crude oil, 60 lbs. sulphate of ammonia.
Strata. Blaes, etc., 12 ft.
No. 5, or Wee Seam. 4 ft. 18 gallons crude oil, 60 lbs sulphate of ammonia

Bibliography.

A full account of the geology of the shale fields may be found in the "Memoirs of the Geological Survey of Britain: The Oil Shales of the Lothians," 1906 Also "The Oil-shale Fields of the Lothians," by H. M. Caddell of Grange, in Trans. Inst. Min. Eng., 1901, or Trans. Edin. Geol. Soc., VIII., p. 116.

The history of the development of the retort is given by Dr. George T. Beilby, F.R.S., in Jour. of Soc. of Chem,, 1897, p. 876. Refining is described in same journal, 1889, p. 100.

PERSONAL.

Mr. J. J. Drummond has returned to Midland, Ont.

Mr. A. C. Flummerfelt, of Victoria, B.C., has been visiting Montreal on business.

Mr. K. Hasekawa, a mining engineer from Japan, who represents the Furnkawa Mining Co., is in the Boundary (B.C.) district visiting various mines.

Mr. A. A. Hassan, of Cobalt, is in Toronto. While engaged by the Victoria Mining Company, Mr. Hasson uncovered several veins on that property.

Mr. T. J. Drummond, president of the Canada Iron Corporation, Limited, has returned to Montreal after a tour through Nova Scotia and New Brunswick.

Mr. Elijah Heathcote, late inspector of mines in the Province of Alberta, has been appointed superintendent of the collieries of the Crow's Nest Pass Coal Company at Coal Creek. Mr. Heathcote was in the employ of the company some years ago at the Carbonado Colliery.

Mr. Jos. L. Danziger, B.S., formerly of the Department Chemistry, Columbia University, has been appointed manager of the Canadian Behrend Dry Concentrator Co. and will have full charge of the Technical Department of the Company. Mr. Danziger is a man of recognized ability in his profession, and has made a specialty of concentration of ores, metallurgy, and industrial chemistry. His recent work in Cananea, Mexico, and at the Lake Superior copper field, perfecting systems of concentration of low-grade ores and mill tailings, was very successful. Mr. Danziger is a firm believer in the principle involved in the Behrend System of dry concentration, based upon familiarity with its operation on many ores, during the past six months, which, with laboratory testing work on Cobalt and other ores of Canada, eminently fits him for economic work in the field of the Company's operations.

Under the present United States tariff the duty on the principal metallic ores is as follows:

Antimony ores	free
Cobalt ores	free
Copper ores	free
Gold ores	free
Nickel ores	free
Silver ores [illegible]	free
Tin ores	free
Zinc ores	free
Lead ores (on lead contents)	1½c. per lb.

The Dannert gas, the new German illuminant for small towns, is made from oil and coke, and is much cheaper than water gas, which it somewhat resembles. The coke used in its production is less than a third of that consumed for a like amount of coal gas. The new gas yields a bright flame, and, as there are no by-products, the process of manufacture is simple.

BROMO-CYANIDING OF GOLD ORES.

In Volume XII. of the Transactions of the Australasian Institute of Mining Engineers there is an interesting paper on bromo-cyaniding of gold ores, by Mr. E. W. Nardin.

At the Hannan's Star mine the process was installed and the plant erected by the London-Hamburg Company. An extraction of 91 per cent. was guaranteed on sulphide ore carrying 15 dwt. of gold. The new features in the process are fine grinding by means of tube-mills, and the addition of bromo-cyanide solution to the vats under ordinary cyanide treatment. The difficulty of obtaining bromo-cyanide solution at reasonable cost was met by the London-Hamburg Company, who supply the mixed salts at a very satisfactory price.

Most of the treated ore was low-grade; hence the percentage extraction appears to be low. But the average value of residues for 1904 and 1905 were 1 dwt. 2 grs. and 1 dwt., respectively, on ore averaging 10 dwts 7 grs. and 8 dwt. 9 grs., respectively. On high grade ore the process was equally successful. In 1903, 15,000 tons of ore from the Brown Hill Extended mine, carrying 4 ozs. gold per ton, and containing telluride, were treated. The average extraction was 95 per cent.

The average cost for bromo-cyanide Hannan's Star sulphide ore was 9.75 pence per ton of ore treated, a saving of 2 shillings per ton as compared with roasting.

The process followed at the Hannan's Star plant in July, 1904, at the time Mr. Nardin took charge, was modified later. At that time the ore from the breaker was dry-crushed in two No. 5 Krupp ball mills, fitted with steel wire screens of 27 holes to the linear inch. From the mills it passed to a mixer, over amalgamated plates, and to a classifier at the end of the tube mill where the slimes overflowed to the slimes pump, and the underflow went to the tube mill. The tube mill discharge was elevated back to the classifier and again separation. The slimes pump delivered to two sets of spitz-luten, the underflows from which passed back to the tube mill, and the overflows to the pointed settling boxes, where the pulp was thickened before passing to the agitator vats. The object was to slime all the ore to pass a sieve of 150 holes to the linear inch. In practice about 5 per cent. would remain on the 150 sieve, but the whole of it would pass through the 100.

There were four agitator vats of 50 tons dry ore capacity each. Each took about 16 hours to fill, representing 75 tons of ore per day through the ball mills. A mechanical sampler arranged between the ball mills and the mixer, cut out a definite quantity of ore periodically. This gave the day's sample.

A vat, when full, was given its charge of KCN. Three hours afterwards a "dip" KCN residue sample was taken and the charge of Br CN solution added. After agitation for 20 hours, lime was added and the vat "pressed." The quantity of Br CN to be added varied according to the residues of preceding vats and the value of the ore being treated.

Every sixth frame in a filter press was sampled, and the bulk sample from the whole vat quartered down to represent the final residue of that vat. The KCN residue was washed on a small vacuum filter and assayed after drying. From the daily ore samples, KCN, and final residues, the total extraction and extraction by plain KCN and by Br CN were determined.

The bromo-cyanide solution is made according to the following equation:—

$$2KBr + KBrO_3 + 3KCN + 3H_2SO_4 = 3BrCN + 3K_2SO_4 + 3H_2O$$

Its action upon the ore is supposed to be as follows:—

$$BrCN + 3KCN + 2Au = 2KAu(CN)_2 + KBr$$

The mixed salt as obtained from the London-Hamburg Company contained:—

40% to 44% of Br as K Br
20% to 22% of Br as $KBrO_3$

A 30-lb. working charge is usually made up thus:—

H_2SO_4	50 lb.
KCN	20 lb.
Mixed salts	36.8 lb.

The KCN is 93% material, and the H_2SO_4 63 per cent. (chamber acid). The solution is made in a closed wooden vesel, fitted with rotating arms and holding 200 gallons. The H_2SO_4 is mixed with a portion of the water first and allowed to cool. The KCN, dissolved in sufficient water to fill the vessel, is then added, and the mixed salts gradually stirred in. The whole is agitated for six hours. A dip sample is taken and tested with a standard $Na_2S_2O_3$ solution, using potassium iodide as an indicator. The standard solution is made so that 1 c.c. equals 0.02 BrCN, and for this about 93.6 grains of ordinary crystallized $Na_2S_2O_3 .5H_2O$ are dissolved in one litre of water.

A solution of copper sulphate is used for standardizing the $Na_2S_2O_3$ solution. The copper sulphate solution is made by dissolving one grain of pure copper foil in acid, converting to sulphate, and dissolving in 100 c.c. water. In testing Br CN solution, 5 c.c. are usually taken, Na_2CO_3 solution added till alkaline, and then acetic acid till acid. A few crystals of KI and some starch solution are then added, and the whole titrated with the standard $Na_2S_2O_3$ solution.

In other mines direct titration with $Na_2S_2O_2$ without first neutralizing the H_2SO_4 is in vogue. The results from this method have been proven to be usually low and irregular.

The vats should be kept under KCN treatment until the KCN residue is known. The alkalinity should then be corrected and the Br CN added.

Br CN does not act well in a too alkaline solution. The best action is obtained when the alkalinity is either about 0.01 per cent. or nearly neutral.

Mr. Nardin sums up the results of certain experiments thus:—

1. The daily ore sample should be taken in the morning and assayed as soon as possible, so as to know what was the value of the ore passing to the vats in the previous 24 hours.

2. The pulp should have a long KCN treatment.

3. A vat should be kept under KCN treatment until the value of the KCN residue is known.

The alkalinity of the vat should then be determined and corrected to 0.01 per cent. by H_2SO_4 before adding Br CN.

5. The quantity of Br CN added should then be determined from the value of the KCN residue, the tonnage of the vat, etc.

6. Lime added to the ore during crushing should be varied according to the alkalinity test after KCN treatment, so that the plant solution tests about 0.02 per cent.

7. Lime water should be made and added to the vats or to the solution from the presses, instead of adding lime to the vats.

8. All metallic iron should be removed in some way from the ore before treatment, as it is both a cyanicide and bromo-cyanicide.

HOSTOTIPAQUILLO AND THE LERMA RIVER.

Written for the Mining and Scientific Press

By Ezequiel Ordonez.

(Editor's Note:—Since a number of Toronto and Halifax men bought a group of mines in this district last winter (among these are the Mololoha and Albarradon, mentioned in this article), it is thought that the article will be of interest to some of our readers. Moreover, the article is a very clear, really vivid, description of a mountainous mining region, and is therefore of general interest. Mr. Ordonez is one of the best known geologists in Mexico, and was formerly Sub-Director of the Geological Survey.)

In view of the geological features and the great extent of the veins, Hostotipaquillo is one of the most important localities in the western Sierra Madre, Mexico. It lies within the District of Tequila of the State of Jalisco, in a mountainous region that is cut by the canyon of the river Santiago or Lerma, and is therefore in the region of high mesas, deeply carved by tremendous erosion. In no part of the country can one better appreciate the true physiographic character of the western Sierra Madre. The plateau has been the result of the piling of volcanic material upon an ancient land surface. There is now a marked difference in the two sides along one portion of the canyon. The south side, of which belongs to the central plateau, is 3,400 feet above sea level, while the opposite side, which belongs to the Sierra Madre, presents elevations that almost reach 6,500 feet above the sea, but on the plateau, long sierras rising above the plains reach and even exceed that elevation. The Santiago River, from the northwest of Guadalajara to Hostotipaquillo, has excavated its own bed, almost at the southern foot of a group of mountain ranges running northwest and appearing to terminate in the central plateau. Only a few of these ranges seem to be continuous farther south, and therefore the Sierra Madre presents different widths to the north and south of that river in the District of Tequila. The width of the Sierra Madre is so far reduced to the south of the river that if it were not for the northwest prolongation of the Etzatlan ranges and the great barranca de Mochiltictic, the Sierra Madre would be interrupted near the parallel of 21 degrees 30 minutes north latitude, to reappear subsequently farther south and with greater vigor in the regions of Pigintos and Mascota. If that interruption had been established there would have been a convenient pass in Central Mexico to reach the Pacific Coast, by only crossing a series of high tablelands from Guadalajara to Tepic.

The Cananea, Rio Yaqua & Pacific Railway, which will shortly connect the Mexican Pacific Coast with the great central plateau, by way of Tepic and Guadalajara, has encountered great difficulties in running through the narrow pass in the Sierra Madre to the northeast of Et. zatlan. Although the final route through that region has not yet been decided, it is important to notice that the railroad will not pass far from the town of Hostotipaquillo. It is said by railroad men that a line to cross the ranges and the barranca will require many bridges and viaducts, which in the aggregate will amount to one and a half miles, as well as several tunnels aggregating about the same length. It is well known that the western support of the great central plateau of Mexico is essentially eruptive in character, and that the mineral resources of that region have been exposed by deep erosion, because the high western edge of the central plateau was first covered with rhyolites and dacites that formed high mesas overlying the veins. These veins, which run through the underlying andesites, diorites, and Tertiary granites, would never have been revealed if there had not been carried off toward the coast a formidable volume of the acidic younger material that composed the marginal mesas. At present these mesas in the Sierra Madre are broken in every direction by deep ravines in which numerous veins appear.

The Santiago River is one of the most important in Mexico, with a length of nearly 1,200 kilometres, having its rise in the eastern corner of the high valley of Toluca from several springs that together form the muddy lakes of Lerma and Almoloya. This river bears the name of Lerma to the point where it discharges into lake Chapala, at about the middle of its course. Chapala was, in former times, a wide valley drained by the river, but at the beginning of the Recent era, a barrier of basaltic lava converted the valley into a large basin. After that the basin was broken by erosion, restoring the river to the ancient channel on its way to the ocean. In cutting its way through the Sierra Madre, the Santiago River exposed a mineral territory not less than 30 miles long in the neighborhood of Hostotipaquillo, the outcrop of veins ribbing the mountains in their slope to the river bed. In all this large territory are distributed the groups of mines called La Cobriza, Cinco minas, Santo Domingo, San Pedro Analco, Mina Grande, Quebradilla, as well as those of El Favor, San Jose, San Francisco, Cabrera, La Castellana, Refugio, Jora Vieja, and others not situated on independent groups of veins. The mineral system is seen to extend without interruption where erosion has already washed away the overlying strata newer than the veins. In this same region, and at short distances apart, are other famous mining districts, such as La Yesca, Bolanos, which, like some of the former, belong to a different political division. The town of Hostotipaquillo, the chief seat of the municipality, is outside of the mining area, as it is situated on the edge of the central plateau where it descends into the canyon. The geological structure of the Sierra Madre and of the central plateau is clearly and simply exhibited in this region. It is seen that the central plateau owes its elevation, as is well known, to the successive heapings of volcanic rocks upon older eroded lands. In this connection, any one could view a beautiful landscape from any of the high peaks that lift their heads about the right border of the Santiago canyon north of Hostotipaquillo. A trip to this region for this sole purpose would be worth the trouble. From a great height, supported by uniform steep slopes the geologist contemplates, over the horizontal line of the plains that form the central plateau, the volcano of Tequila with a great lava mass crowning its summit. The immense cone of this high volcano appears to repose on a large platform of lava, which is bathed by the waters of the Magdalena Lake. The nature of the ground is as suggestive as the landscape; rhyolites and dacites are the constituents of the mesas, and on such material rests the entire volcano of Tequila. These rocks lie on the Miocene andesites. In these andesites are found the veins along the lower level near the river and in the high hills in the neighborhood. The mountains are also frequently

crowned by remnants of rhyolite mesas in the form of bluffs. In the steep walls of the canyon are found blocks of columnar basalt in the form of cliffs and cornices; these are the remains of a basaltic plain over which the present river flowed, 1,200 feet above its present bed, and for a distance of no less than 50 miles.

The Rio Grande de Santiago has three times re-excavated its own bed in its passage through the Sierra Madre. The river first started by flowing through a large valley bounded by mountains of eruptive rock, because it must be stated that the rhyolites that formed the mesas did not spread over prolonged andesitic sierras, but over independent *massifs* close to each other, each with its own history of volcanic evolution, although many of the *massifs* were synchronous. The Miocene Valley became continually deeper by erosion, and by displacements due to faults along the dikes so numerous in the mining district of Hostotipaquillo. In the Pliocene era, the great overflow of rhyolite constituting the mesas, filled the basin of the rivers and interrupted the course of the waters, which soon commenced to run again over the mesas, filled up the basin of the river and interrupted the course of the waters. These soon commenced to run again over the mesas as well as underground, following their old channel. Near the coast, the river precipitates itself in falls and rapids, which continually work backward, as has been done in the east by the falls of Juanacatlan on the same river near Guadalajara. This waterfall, called the Niagara of Mexico, exists where the great stream ceases to serve agricultural uses and is converted into a source of motive power. The backward erosion of the waters, assisted by movements in block, have ended by re-establishing the old river bed, for the second time, in the form of a gorge with cliffs, afterward becoming gentle slopes. Lastly, this old valley has become the scene of a new geologic change. The uniform slope of the bottom favored the flow of a stream of basaltic lava many miles long and 100 to 300 feet thick. The erosion cut through and brought down these basaltic masses, allowing the river to return to its old bed. This third period of erosion in the Pleistocene and Recent eras, appears to have been more intense and prolonged than the two earlier, seeing that after the waters reached their former bed, they have continued their work of excavation, so that it is now 1,000 feet lower.

The State of Jalisco, Mexico

In this brief history of the Rio Grande de Santiago no mention has been made of the period in which the veins were formed; this probably was immediately before the appearance of the rhyolites forming the mesas. Nor has mention been made of the phenomena connected with the appearance of the dikes, some of which are older and some newer than the veins, nor of the fluctuations of surface-elevation on a large scale in the Sierra Madre.

The mining region of Hostotipaquillo has been worked ever since the commencement of the colonial period

in spite of the rough character of the ground, of the vicinity of warlike Indians in earlier days, and of the entire absence of roads. The last mentioned difficulty exists even at the present time. In the year 1804, Humboldt refers to the Hostotipaquillo mines as celebrated, and in the reporst presented by the Mining Deputatian of Hostotipaquillo to the Provincial Mining Board, in 1824, ample data with respect to the old mines denominated La Famosa, Deseada, El Refugio, Mololoha, El Tabor, La Espada, San Jose, Quebradilla, Mina Grande, and others were given. Some of these old mines are now undergoing development with large capital in the hands of companies, mostly American.

A complete list of all the companies now contributing

to the activity of the district cannot be given, but several are worthy of special mention. The Cinco Minas property, belonging to Martinez and Cardenas, has under development four or five mines. The property represents an approximate value of 500,000 piastres. Part of the ores from the Cinco Minas are treated in the Hacienda de Santo Tomas by the patio process. The El Favor Mining Co. operates an extensive property, of which the El Favor mine is the chief. Some of these mines show ore to the value of several million pesos. The Company is planning the erection of a large concentration and cyanide plant in which it will treat its abundant supply of low-grade ores. It will utilize a part of the water-power to be developed by the plant of the San Pedro Analco Co. The Cabrera group of mines belonging to the Virginia Mining & Milling Co., has been producing from the Cabrera mine for many years. The Company is now erecting a concentration and cyanide plant to have a daily capacity of 200 tons, and will obtain power from Santiago river. The mill will be erected close to the river bank, and the ores will be brought down from the mines by a cable tramway. The San Antonio Mining Co. is operating the San Jose, Las Palomas, San Antonia, and other mines. It is also operating the small Socorro mill, which is one of the oldest in the district. The San Antonio mill has 10 stamps, partly driven by electricity. The process employed is the patio, and the tailing is concentrated in the old Mexican way. The Jalisco Mining Co. has the Mercedes, Dona Ema, and other mines close to the old Mololoha and Hundido mines. Work is being pushed by an American company in the famous Casados mine. The exploratory work recently started has led to the discovery of a large quantity of ore. The Company is erecting a concentration and cyanide mill, besides exporting high grade ore. The San Felipe Mining Co. operates a mine near the village of Jocotlan. It also possesses a small concentration and cyanide plant, which is equipped with stamps, Bryan mills, and other modern machinery. The Santo Domingo Mining Co. has operated an extensive group of

mines, and completed considerable development work with the help of machinery. The principal mines operated by this Company are the Santo Domingo, Esperanza, Nombre de Dios, and El Favor. It is said that the Company has temporarily suspended work. The Castellana mines have for some years past been worked successfully with English capital. They now have a mill, driven by electric power, with a capacity of 40 tons per day. This Company utilizes a small part of the waters of the Santiago river for motive power. The Cia. Minera de San Pedro Analco operates an important group of mines on the right bank of the Santiago with satisfactory results. Some of the mines in this group are considerably developed. The San Pedro mill has six-stamp-batteries which crush 60 tons per day. The ores are treated by the patio process, although wtth rather high losses of silver.

As a general thing all the mills in the Hostotipaquillo district which treat the ores by the patio process give poor returns, as these ores are not adapted to that treatment. The cyanide process will give better results supplemented by concentration. The San Pedro Analco Co. has undertaken an important work in the construction of a dam 300 ft. long across the bed of the Santiago river, creating a fall of about 25 ft. Three turbines will be set up to handle a large volume of water, and develop 1500 hp. in an electric plant. The construction of this dam across the river reflects great credit on the builders and on the company. They have had to overcome enormous difficulties and incur heavy expenses. When the power plant has been installed, the San Pedro Analco Co. will re-construct its mill in accordance with modern principles.

Carlos Romero, of Eztatlan, Jalisco, is the owner of an important group of historic mines, such as Albarradon, La Famosa, Deseada, La Espada, La Quebradilla, La Descubridora, and others. He was formerly the owner of the Mololoha mine, which is famous in local history. The mining region of Hostotipaquillo already involves a valuation of nearly 35,000,000 piastras.

The veins in this region traverse andesite, dacite, and seldom diorite, and it is not a rare thing to find the veins also in breccia and in andesitic tuff. As a general rule, the veins are wide and continuous, especially in the eastern parts of the district, where veins are found with a width of 34 ft. The matrix is quartz and calcite. Large bonanzas were found in the old mines, but the dissemination of the ore throughout the veins gives this district special importance. Its future depends on the utilization of concentration, and cyanidation. As a general rule, the ores carry little gold, the most valuable mineral being silver sulphide, sometimes accompanied by galena, pyrite, and blende. There are also small quantities of copper ore, carbonate near the surface, and chalcopyrite below. In the oxidized zone, where secondary modications have taken place, the veins contain manganese, oxides, ferruginous clays, native silver, and in some cases, chlorides and bromides of silver. Practically the deposits form a series of linked veins running northwest, following the general orogenic axis of the region. The veins are frequently intersected by faults, but displacements are not great; they are also cut by dikes. The veins sometimes follow the direction of the older dikes for a long distance.

The enormous extent of the Hostotipaquillo mining region, the number and width of its veins, the abundance of its low-grade ores, the facilities afforded by the topography, the abundant natural resources, the completion of the railroad, will make Hostotipaquillo one of the most important mining districts of Mexico. For motive power, the Santiago river offers immense possibilities. It is reported that the Federal Government has given concessions for about 200,000 hp. to be developed along this stream.

EXCHANGES.

The South African Mining Journal, October 31, 1908.—In this number of our contemporary we find instructive records of mining and milling costs. One example is worth quoting. Knights Deep mine during the year ending July 31st, 1908, had an ore output of 504,890 tons; 200 stamps were kept in commission. The total yield of gold was £680,561, or an average of 26s. 11d. per ton. This average yield was lower by 2s. 1d. than during the previous year. But increased capacity and a large reduction in working costs brought the profits per ton up from 8s. 2d. to 10s. 1d. Instead of a 10 per cent. dividend a 25 per cent. payment was made. A payable ore reserve of 1,438,000 tons has been developed.

The Mining World, November 28, 1908.—"Methods Used in Sealing Off Underground Water," is the title of a paper by Edmund B. Kirby.

Known methods of sealing off or reducing incoming flows of water have not found any wide application in mining. They are generally excessive in cost and uncertain in result. Mr. Kirby's patent consists primararily in introducing into subterranean flows of water entering a mine, any kind of subdivided matter capable of being carried by those flows towards their exits and of being deposited in and choking up the passages leading to these exits. Finely subdivided clay, held in suspension by the water, is mostly preferred. Other materials, such as sand, wilth tailings or slimes, cement, saw-dust, horse-manure, chopped hay, etc., may be used.

This method has been employed to seal water flows for a distance of 240 feet,

---

The Mining Journal (London), November 21, 1908.—A most interesting leading article is our contemporary outlines, "The Future of New Zealand Alluvial Gold-fields." It is stated that "it is only by such painful experience of diminishing profits as the fields have been and are still undergoing that they can attain to a healthy condition, and that investors can see for themselves that they are not throwing money into a hole and losing it."

Apparently both dredging and sluicing operations are not advancing; but local interests and the geological survey have been and are most active in exploiting new ground and in investigating systematically the whole field. Confidence is felt that dredging and sluic-

ing will be carried on in the future with much better prospects of success.

Electrochemical and Metallurgical Industry, November, 1908.—In the course of a paper on "Electrolytic Gold Refining," in this number of our contemporary, Dr. Emil Wohlwill takes exception to certain deductions of Dr. J. W. Richards. Dr. Wohlwill also reaches the following conclusions concerning electrolytic gold refining:—

1st. Before employing the process and before calculating its requirements and results, it is necessary to make a preliminary investigation as to whether the available raw gold alloy is suitable for electrolytic treatment.

2nd. If the raw gold alloy is found to be suitable, experience must decide on the current density to be used, according to the composition of the anode material.

3rd. If interest is to be charged for the gold, it is necessary and easy to modify the conditions of operation in such a way that the interest charge becomes a minimum.

The Engineering and Mining Journal, November 28, 1908.—Walter Renton Ingalls discusses most illuminatingly the question, "Has the value of gold depreciated?" Mr. Ingalls opposes the theory that the rise in commodity prices is due to the increased production of gold. He contends that (1) a great increase in gold production may occur without increasing wages and without attracting any large number of men away from previous occupation; (2) the profit derived from the production of gold is rarely expended at the place of production, but is distributed among many investors in the commercial countries of the world; and (3) much of what is considered to be profit is really not so.

Mr. Ingalls points out that labor unionism and the increasing inefficiency of labor have contributed to enhancing the prices of commodities. "It is scarcely to be doubted that the prices of commodities will continue to fluctuate in the future as they have in the past, independently of the world's production of gold, the effect of which upon prices at any time in the world's history has been but ephemeral and has been due to conditions that long since ceased to exist."

INDUSTRIAL SECTION.

Mine and Quarry, October, 1908.—The Sullivan Machinery Company issues this bright monthly. It contains several specially written and particularly practical articles. One of these, entitled, "A New Departure in Mine Power Plants," by George M. Crawford, describes the installation of the Cowanshannock Coal and Coke Company, at Yatesboro, Pa. Here is a central electric generating plant from which current in wired to substations, where the air compressors and motors that drive the machinery in each part of the field are located. All the air-compression and coal-cutting machinery was purchased from the Sullivan Machinery Company.

Canadian Westinghouse Co., Limited, Hamilton, Ont., Circular No. 1126.—Westinghouse Types C and CL transformers for pole mounting are illustrated in this circular. These distributing transformers operate in oil. Temperature rise is thoroughly guarded against, and complete insulation is thoroughly provided for.

Catalogue No. 11, Pennsylvania Crusher Co., Philadelphia, U.S.A.—The Pennsylvania Hammer Crusher for crushing coal is susceptible of quick adjustment. No shut down is necessary. By a turn of a hand wheel the cage is raised closer to the hammers. This is only a matter of seconds. In case of choking, or when inspection is necessary, the cage may be instantly dropped.

Crushing is becoming more and more essential as a preparatory step to coking, whether the coal is to be washed or not.

The Pennsylvania Crusher Co. also manufacturers the Pennsylvania Bradford Coal Cleaner, Coal Cleaner and Hammer Pulverizer (combined), Magnetic Separator, Rotary Crushers, Single Roll Crushers, Rock Crushers, Portable Rock Crushers, etc., etc.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.—The Dominion Coal Co.'s output for November was only 244,000 tons, which is 90,000 tons less than the previous November. The output for the year to date is 3,347,000 tons compared with 3,317,000 tons at the end of November, 1907. From present indications the tonnage for the year will be practically the same as that of last year, or slightly over 3½ million tons. It was anticipated at the beginning of the year that the output would reach 3¾ million tons, but in the face of the depression that has been general over the Dominion it is really a matter for congratulation that the Company have found it impossible to maintain the same output as in the previous twelve months, and to stave off the inevitable period of short work for so long. The break comes after a long and uninterrupted spell of prosperity, and it is confidently hoped that it is but temporary. Indications are not wanting of a return of confidence in the United States, and the mines there are beginning to feel the benefit of the increased demand for their product. This will relieve to some extent the persistent American competition which has been felt all Summer in the Montreal and Toronto districts, and which has had a grave bearing on the trade conditions in Cape Breton. It is perhaps not fully realized how very strenuous this American competition is becoming. In slack times when small profits or sufficient return to cover expenses are gladly accepted in order to keep the mines in operation and retain the workmen, it can be easily seen how convenient a dumping ground the Upper Canadian provinces and the large centres of population at the head of the Great Lakes may become for American operators. No one who has given thought to this matter but must confess that Canadians have all to gain and nothing to lose by weakening their tariff barriers. They are already but too weak to withstand the pressure of the enormous coal resources of the United States until such

time as our own coalfields shall have been fully discovered and developed. Nova Scotian coal owners at elast cannot afford to coquett with their friends in the States, nor can their workmen. The trade that is providing work for the members of the U.M.W.A. is the very same trade that is causing slack time in Cape Breton. There can be no friendship or reciprocity between American and Canadian coal interests, without serious detriment to the latter. The interests of master and man are the same in the matter. Those members of Canadian labour organizations or of trade leagues who favor amalgamation with the United States might profitably read the fable of the lion and the mouse that they may remember in the old "Fourth Reader." It is an illuminating lesson to take a good atlas and compare the cities, towns, and villages south of the frontier of Canada with the sparse lettering above that line, and then to study the mineral maps of the U. S. Geological Survey: Virginia, Pennsylvania, Alabama, Tennessee, etc., etc., side by side with the publications of our own Geological Survey. True it is that our Canadian mineral resources are yet unknown and may be only dimly guessed at, but it is also true that the stronger our tariff walls, the more quickly will they be discovered and opened up. Charity begins at home, and when one is dealing with a nation that has defied individualism and monetary success, we cannot afford sentiment. In Nova Scotia at any rate our ways lie separate.

U. M. W. A. vs. P. W. A

4th December, 1908.

The event of the week in the mining towns has been the ignominious failure of the perjury charge preferred by the representatives of the U. M. W. A. against the Grand Secretary of the P. W. A. It would tax the impatience of any reader to explain on how flimsy and intangible pretexts the charge of perjury was based. It is a fortunate thing for the purses of the ratepayers that such tiresome and perfectly useless cases are not often tried. The amount of legal hair splitting and learned argument that can be gathered around a point which the ordinary person would settle in five minutes puzzles a good many people. It will puzzle still others when the bills have to be paid.

The remarks of Judge MacGillivray on the situation are worthy of quotation. He referred to the good record of the P. W. A. and expressed his surprise at the unity and continuity exhibited by the history of this organization since its formation 26 years ago. It must have had good leaders and good managers to have accomplished all it had done. It was a great pity that any leader of the Association should be brought before the Court on a criminal charge as the result of a difference among the members, and that the funds of the membership were being frittered away in litigation. In finishing his judgment his Honour said: "The prisoner has been put in a position in which he should not have been placed, and in which he would not have been put except for the action pending against the Grand Council—were it not that there was too much anxiety by Counsel to get information for use in the Civil Court. I have already, in other cases, had occasion to condemn this practice. Spite and revenge are not the law of the land, and should not be the foundation for putting into effect the processes of the law, especially when the Crown must pay all the expenses of the trial except the costs of the prisoner's Counsel. In my opinion if this prosecution had been founded on the allegation of the prisoner having committed the offence and had not been ancillary to another action it would never have been brought".

An interesting sequel to the trial is an open letter from the Grand Secretary, in which he charges the local organizer of the U. M. W. A., one of the leading spirits of the prosecution, with misappropriation of the funds of Pretoria Lodge, and states that he himself had protected this man from arrest and criminal prosecution.

What will most of all appeal, we think, to the Nova Scotian members of the P. W. A. in the learned Judge's remarks is his advice to steer clear of international union. We have on several occasions expressed the same view in stronger terms, and it is gratifying to find this opinion is also held by a gentleman so competent to give one. Canadian labour unions cannot afford union with those of the United States, particularly when engaged in trades that enter into commercial competition. If the iron vessel and the earthenware pitcher go to the well together some day something will be broken. Professor Shortt, whom no one can justly accuse of partiality, has recently expressed himself as opposed to international union in this matter and as favoring the fostering of a national spirit in trades unionism as well as in other matters pertaining to the welfare of the people.

No empire in the world's history was ever founded on a truer democracy than that of our own, and nowhere in all its vast realms has it produced a fairer flower than in Canada. We do not want the peculiar methods favoured by American unions to destroy the innate love of law and order which characterizes our people. We can dispense with that feature of industrial warfare which ranges on one side the deputy sheriff with his loaded Winchester, and on the other murder, bomb-throwing and the red rage of unbridled anarchy. They are foreign to our country and our empire, and we think our miners will be wise if they do not join hands with organizations that use such methods.

BRITISH COLUMBIA.

Rossland.—The situation at the Le Roi No. 2, Ltd., is improving. The official confirmation is now at hand regarding the strike on the 500-foot level of the rich big ore body that was pierced by diamond drill. Several wide veins were cut, and assays from the core gave returns of as high as $73 per ton. The diamond drill hole was put down in the direction of the top of stope No. 3 on the 700-foot level.

During the month of October the Le Roi mine here made a better showing than it has for many months. It is estimated that the profits on the company's operation were in the neighborhood of $50,000. During that month 6,861 tons of ore were shipped to the Northport smelter, that returned an average value of $18 per ton. During the year last reported on by the company's directors the average value of ore shipped was $10.02, but a much larger tonnage was shipped than during the year 1906, when the average value per ton was $10.50. However, it is pleasing to see that the Le Roi can, with a little effort, get in and make a good showing once in a while. The amount expended for development during October was lower than it has been running, $1,500. It is important to note in connection with this month's work that most of the ore was mined in the 1,650-foot level of the Le Roi, where the gold values predominate, the copper falling away to some extent.

Ore shipments from Rossland district has been rather heavy during the last few months, and it now looks as though the Centre Star group would exceed their total tonnage for last year, by the 31st of December next, to the extent of over 50,000 tons. The Le Roi No. 2, Ltd., shipments will not differ much one way or the other, while the Le Roi record will fall about 35,000 tons under the shipments for 1907. But this may not have an important bearing on the moneymaking features of the company's operation, as the ore that was shipped should prove to be of a higher grade than that sent to the smelter during 1907.

The first assessment levied by the White Bear Company under the new organization has been paid up. Another assessment should place the company in shape to go ahead with the

work that was planned prior to the last closing down. The shaft will be deepened, with the prospect of getting into rich ore regions that are thought to lie at depth on this property. If the White Bear ever did stand a chance to make a paying mine, it is with conditions as they now are at the mine. Some good ore has been opened up, but not in what is known as large quantities in this camp of large lodes. As the ore has improved with depth, it looks as though the hopes of the mine lay still deeper in the ground.

Mr. W. D. Matthews, of Toronto, president of the Consolidated Mining and Smelting Co. of Canada, visited the Centre Star group and the company's smelter at Trail during the past week. Mr. Matthews was well satisfied with the way affairs were moving with the company's property in this section. There is little doubt but that the report of the Consolidated for the last year will prove favorable, as things have gone well with the mines and smelter of this organization during the past twelve months.

Boundary.—The declaration of a 2 per cent. dividend by the directors of the Granby Company was received with satisfaction throughout this district. This is the second dividend the Granby Company have paid out of their earnings this year, which goes to prove that the expense of mining and smelting has been reduced by the management to a minimum figure, this being absolutely necessary for the realization of profit when selling copper on a low-priced market. The Granby Company have paid ten dividends since December, 1903, amounting in all to $3,508.630.

The entire battery of eight furnaces has been in operation at the Granby smelter during the past week, including the remodeled furnace, which is giving good results.

Ore shipments from the Granby mines alone should pass the million ton mark before the end of the year. This year the Granby will exceed the shipments of 1907 by over 400,000 tons. As it is officially stated that there is a greater reserve of ore, developed by diamond drill and other development work, in the Granby mines than they have shipped so far this year, there must be nearly a million tons of ore "in sight."

Shipments from the Mother Lode will exceed those for 1907 this year by approximately 100,000 tons, while the shipments from the Oro Denoro will exceed the output of the Emma for 1907 by 65,000 or 70,000 tons.

Mr. Frederick Keffer, consulting engineer for the British Columbia Copper Co., with a small staff of assistants, has made an examination of the more important of the mines of the Dominion Copper Co., including the Brooklyn, Mountain Rose and Sunset. While no information has been given out, it may be that one of the big consolidations would like to lease these mines, treating the ore in the larger and more up-to-date smelters than that of the Dominion Copper Co. at Boundary Falls. The proposition is feasible.

The output of the Snowshoe mine is now being divided between the company's smelter at Trail and the Greenwood smelter of the B. C. Copper Co. This is along the lines that the output of the mine was handled last year.

The National Trust Co., in the Supreme Court at Vancouver, has asked for judgment on the $800,000 mortgage they hold of the Dominion Copper Co. The application was opposed by counsel. Mr. P. F. Roosa, manager and provisional liquidator for the Dominion Copper Co., has gone to New York City in connection with reorganization matters.

With the ore sent from the Boundary during the last couple of weeks the Boundary ore shipments pass the 7,000,000 line. The Granby shipped over 65 per cent. of this heavy tonnage, the Mother Lode mine about 20 per cent., and the other smaller properties in proportion.

The Keremeos Copper Co., controlled by Spokane mining men, has been registered as an extra-provincial company. A contract has been let for a 1001foot tunnel. The company has three promising claims in the Similkameen.

Nelson.—The mining interests of the Slocan are looking forward with some interest to the decision of the Supreme Court of Canada in the case of Byron S. White Co. vs. the Star Milling and Mining Co., of Sandon. It is expected that this case will be disposed of by the court before the holidays, and as it will establish a precedent which will affect Slocan mining to quite an extent in the future, hence the interest. It seems the B. S. White Co. followed a lode, of which they claim to have the apex, which dipped into a claim owned by the Star Company. The apex may be traced through several claims of the White Company on the surface, and indications of ore are easily followed along the vein on the 300-foot level. There is a barren strip on the 600 level where the ledge has faluted and, as the writer understands the case, the point of contention is whether this barren strip extends to the surface and makes what legally may be termed another vein, or whether the ore body would be designated as one vein that had faulted and the apex rights having been established that the company having the apex may follow that vein into the vertical lines of the adjoining property.

This will be the first important decision that has been given by the Supreme Court in British Columbia mining law, and the outcome is being looked forward to.

Several Spokane mining men visited the reduction works of the Canada Zinc Co. during the past week, and they say that if the process proves a success for the treatment of zinc ores, it is very likely that a similar plant will be built at Coeur d'Alene, Idaho, to treat the lead-zinc ores of that district.

Mining men here have noted with interest the resolutions passed by the trustees of the Spokane Chamber of Commerce and Denver and Missouri interests protesting against the reduction of the tariff protection now on lead and zinc products, as the matter, to a small extent, affects the zinc-lead miners of the Slocan at the present time. The present duty is 1½c per lb. on lead ore and 2½c per lb. on lead bullion. Very little lead is shipped to the United States for consumption, but there is an occasional shipment to some point in the States for manufacture, and when the manufactured article is exported from the United States a rebate is granted, a small sum being withheld for charges.

The power lines are now into the Silver King mine, and the electrically operated pumps will soon have the mine unwatered. As soon as this is accomplished it is the intention to begin work on the lower levels of the property.

The zinc smelter of the Canadian Metal Co. at Frank is being dismantled, and will soon only be a matter of history. While the company received what appeared to be valuable concessions at Frank, they were too far from the source of the product they were to treat, and the freight rates had much to do with the failure of the enterprise.

Even New Denver is sharing in the prosperity that is noticeable in the Slocan. The Molly Hughes has been again opened up and a small crew put to work.

A two weeks' run of the four-stamp mill at the Nugget has resulted in a $5,000 gold brick, one-half of which it is estimated is clear profit.

About $250,000 of French capital has been placed into alterations and improvements about the Blue Bell in the last 18 months, and the property is now in good form for a heavy production. The stamp mill (110 tons), which is capable of treating a large tonnage, has been running more or less steadily

since July, and has treated 15,000 tons of Blue bell ore. The company has shipped over 2,000 tons of concentrates to Trail smelter.

The Iron Mask mine at Kamloops has been sold to West Duluth mining men, and a force of twenty men put to work. It is the intention to work about 100 men at this mine in the spring. Lack of smelter facilities has handicapped the Kamloops mines considerably in the past, and it is now thought that a small smelter will be erected near the Iron Mask. This would prove a great stimulus to the Kamloops copper properties.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney Mines.—Owing to scarcity of shipping the Nova Scotia Steel and Coal Company has closed all but its No. 3 Colliery.

Halifax.—It is expected that the new Technical College will be completed next July.

NEW BRUNSWICK.

St. John.—Chatham has been provisionally selected by the Canada Iron Corporation as a shipping port for their iron ore from the deposits near Bathurst. It is possible that a smelter will be erected there also.

ONTARIO.

Sault Ste. Marie ,Dec. 3.—The steel plant of the Lake Superior Corporation closed down this morning at 6 o'clock, according to the statement of General Manager Franz, from lack of orders. Rolling for the last order of the Transcontinental Railway was finished this morning.

The management announces that the plant will re-open on January 1. The blast furnaces will continue operating in full force.

Sudbury.—The Crystal stamp-mill, near Lake Wahnapitae, has been closed temporarily on account of shortage of fuel. During the recent forest fires the Company's entire stock of cordwood was burned.

Cobalt.—The Flynn property, near Cross Lake, has been purchased by a small syndicate of Toronto men, under the name of the Pontiac Mining Company. Very little silver has been discovered. One vein of calcite and smaltite has been worked to a small extent.

The concrete foundations of the O'Brien concentrating mill has been completed. The frame work is now under construction.

Development work on the properties of La Rose, Cons. Mines Co. during the month of October was as follows: La Rose mine, 493 feet and 764 cubic yards of sloping. Princess mine, 104 feet. University mine, 18 feet, some open cut work. Violet mine, 1,090 feet of trenching, besides a small amount of open cutting.

An average number of 242 men were employed on the company's properties during the month. A contract has been entered into with the American Smelting and Refining Co. for the treatment of La Rose low grade ores at Denver. This contract is more favorable than the schedule under which La Rose ores have been marketed in the past.

The Green-Meehan and Red Rock Cobalt concerns, which have been amalgamated, will be called the "Mount Royal" in future.

BRITISH COLUMBIA.

Frank.—The zinc smelter of the Canadian Metal Company is being dismantled.

Michel.—The pay roll of the Crow's Nest Coal Co. for Michel for October is $97,800.

Nelson.—Where a year ago only the Queen mine and a stamp mill were working on Sheep Creek, at present there are six others, the Kootenay Belle, Bonanza, Mother Lode, Golden Fern, and Nugget. The Queen has improved its water supply and has added 10 stamps to its mill. Two 20-stamp mills are projected, the first for Mother Lode and Kootenay Belle, together, and the second for the Nugget.

Sandon.—Up to November 28, the Reco mine has shipped 456 tons to the Trail smelter. At that date there was a pile of 5,000 sacks awaiting the first substantial fall of snow when rawhiding will be commenced. There is much ore, also, broken in the stopes, and the chutes are full. It is believed that the Reco can ship a carload a day during the winter. Since 1905, during which year the Reco paid $20,000 in dividends, the mine has not been worked with uniform success. But last spring it was leased to an Italian miner, who is doing exceedingly well.

Nelson.—The second Relief mine, opened first in 1896 by Finch and Cameron, is being worked successfully under lease by Messrs. Hudson and Bell. A 10-stamp mill is in operation. The vein worked ranges from three feet to 12 inches in width. Nearly all of the ore is reported as payable.

The Mother Lode mine in the Sheep Creek camp, is shipping good ore to the smelter.

Rossland.—Electric power is being installed at the Silver King and Victoria mines, near Nelson.

A 500-foot tunnel is to be driven into Wallace Mountain to cut the veins of the Bell Mining Company's properties.

Vancouver.—Near the old Cornell workings, on Texada Island, abounded twelve months ago by an English syndicate, after a uarter of a million dollars had been spent, it is reported that a large body of copper-gold ore has been encountered. Insufficient development has been done to make any final statements about the size and character of the vein. But it promises well.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The continued depression in the South Wales coal export trade is being severely felt, and large numbers of the coal miners are on the verge of starvation.

Wales is the only gold-producing area in the British Isles, and the output is not large. In 1907, 12,978 tons of gold ore, valued at £5,625, were produced, as against 17,384 tons, of the value of £5,343, for the previous year. It was practically all raised in Merionethshire, where it occurs in quartz veins traversing the Cambrian rocks.

The Durham Coal Trade Conciliation Board has reduced coal miners' wages 3¾ per cent.

FRANCE.

Important experiments as regards coal-dust explosions were recently made at the French Government's testing galleries at Lievin, which demonstrated that grisontine couche, employed for the last two years in the coal mines of Northern France, is a safety explosive, and that by placing in sections deposits of inert matter throughout the galleries danger in case of accidents was limited.

The French Government has proposed important amendments to the mining laws, which will open the way to the acquisition of mines by the state whenever such a step appears advisable.

The first steel ingot ever cast in Denmark was recently produced at the new works of Messrs. Burmeister & Wain, at Copenhagen.

RUSSIA.

Large quantities of Russian iron ore have lately been shipped to Silesia, but in view of the injurious effect of this trade on the Russian iron industry, the Government has decided to enforce strictly the existing regulations prohibiting it.

The Societe des Usines Metallurgiques de Moscow has erected tin-plate plant and imported 27 workmen from South Wales.

AUSTRO-HUNGARY.

The Austrian mining authorities have issued new regulations for the prevention of fire in the oil districts, compelling every oil well owner to provide adequate storage facilities for his output.

UNITED STATES.

Two new coal fields have been discovered in Indiana. Northwest of Bloomfield, Green County, workmen drilling for water struck a vein of workable thickness at a depth of 130 feet, and in the course of drilling a well in Bartholomew County a farmer encountered a rich vein 25 feet thick about 100 feet down.

Cripple Creek, Colo., bids fair to reach the quarter-billion mark in production by the close of the year, the total output of the camp up to the end of October being $248,374,312. The present year's output so far has exceeded that of the entire years 1907, both in tonnage and value, the yield for the ten months ending with October being 632,426 tons, valued at $13,496,299. By the adoption of modern methods in the treatment of low-grade ores, thousands of tons are utilized that were formerly thrown out on the dump.

Two new quicksilver mines are being opened on the Pacific Coast. One is the Florence Mack, west of Coalinga, Fresno, County, Cal., and the other near Ione, Humboldt County, Nev., where a reduction plant is being installed.

On November 28th an explosion occurred in the mine of the Pittsburg-Buffalo Coal Co., at Marianna, Pa., which resulted in the death of 135 men. Immediately before the disaster a mine inspector had completed a two-days' inspection of the workings, which revealed no cause for apprehension. The force of the explosion was so great that woodwork about the mouth of the shaft was blown a distance of 2,000 feet. Most of the victims were suffocated by smoke, as the explosion put the ventilating fans out of order.

MEXICO.

A rich telluride gold deposit has been discovered in an almost inaccessible bluff in the Arteaga mining district in the western part of the State of Chihuahua.

JAPAN.

The metallic production of Japan for the six months ended June 30th was as follows: Gold, 35,905 oz.; silver, 1,706,443 oz.; copper, 24,348,834 lbs.; iron, 18,318 long tons. The exports of copper amounted to 2,458,253 lbs.

AUSTRALASIA.

The smelting companies of Wallaroo, Australia, have decided to use German coal in future on account of its relative cheapness as compared with the coal of New South Wales. The difference is due to the cheapness of labor in Germany.

The low price of silver has resulted in the discharge of a number of miners at the Colon Peaks, Yerranderie, N.S.W., as the cost of production leaves no margin of profit at present rates.

A rush to the Poseidon country, Victoria, has set in owing to some rich finds of gold near Tarnagulla.

COMPANY NOTES.

At the recent Dominion Copper Co. meeting there was represented approximately $500,000 of the $800,000 bonds. General Manager White, of the National Trust Co., presided, and stated that the property is likely to be sold.

No plan for reorganization was presented, but the following committee of bond-holders was appointed to examine the situation and report: Hon. W. W. Foster, John A. Sleicher, Warren Castle, Prof. Stebbins, H. H. Melville, and Messrs. Williamson and Shields.

The La Rose Consolidated Mines Co. announces that a contract has been entered into with the American Smelting and Refining Co., for the treatment of the low grade of the former, at Denver. This contract is more favorable than the old contract.

The Kerr Lake Mining Company has declared the regular quarterly dividend of 3 per cent. payable December 15. Books close December 6, and re-open December 17.

The Cobalt Central has announced officially that a dividend of 2 per cent. will bedeclared in December.

The directors of the Buffalo mines met yesterday and declared a dividend of 5 per cent. and a bonus of 1 per cent. per month for the current quarter, this being at the rate of 32 per cent. for the year.

The Cobalt Silver Queen Co. has decided a quarterly dividend of 2 per cent. Heretofore the company has also declared an additional 2 per cent. bonus at the quarterly period, but owing to the fire on July 12 last this extra disbursement has been suspended for the present.

The shareholders of the City of Cobalt Mining Company at a meeting on November 30 authorized the directors to increase the capital from $500,000 to $1,500,000, each shareholder to receive three shares for every one now held. They also decided to issue the stock now in the treasury to the shareholders pro rata, being 10 3-4 shares for every hundred shares.

The directors decided after the meeting to pay a 10 per cent. dividend on the 15th of January on old capital; $500,000, and to add a large quantity of machinery to the plant. The

last dividend was five per cent., or twenty per cent. per annum. The new rate represents forty per cent. per annum.

After a lengthy session on Nov. 30th, the directors of the Crown Reserve Mining Company the directors decided to pay a dividend on the capital stock, of 12 per cent., and a bonus of 4 per cent., making a total disbursement of 16 per cent. to stockholders.

The twelve per cent. dividend is for the half-yearly period, ending December 31, 1908. In future the dividends will be on a six per cent. quarterly basis, which is at the rate of twenty-four per cent. per annum.

Bonus payments will be made quarterly and will be in accordance with the surplus earnings of the company. In this respect it is interesting to note that, after allowing for the current disbursement, the company will have by the end of this year in cash on hand and owing by the smelters in excess of $250,000, while there will be at least $100,000 of ore in the ore house. The surplus would be sufficient to pay another twelve per cent. bonus on the company's stock.

The company has paid for plant and equipment houses and miscellaneous expenditure out of earnings, and have been working on proper mining methods for less than eight months of the year.

The books close December 15 to January 15, both days inclusive, and the dividend will be paid January 15. The annual meeting will be held January 13.

THE CONIAGAS MINES, LIMITED—DIRECTORS' REPORT.

To the shareholders of The Coniagas Mines, Limited:

Gentlemen:—

During the past year your Mine has been operated without interruption with a force of about 125 men.

The Concentrating Mill has been extended and twenty stamps have been installed, with an economical gas engine to run the mill, and increased concentrating machinery. Ten more stamps will be installed immediately, and the capacity of the mill (and therefore of the mine) will be incerased to about 90 tons per day, as against about 45 tons during the past year.

Additional camp accommodation for the men has been provided, and many dwellings have been erected and rented to the married employees as shown on plan accompanying this report.

A new shaft has been sunk near the mill to the 150 feet level and all ore is hoisted in this shaft and dumped direct into the mill.

The ore in the lower level is found to carry equal values to that found in the upper level, and the accompanying plan shows that a large amount of ore has been developed on that level without any dead work whatever, veins having been found running in directions suitable for the proper development of the mine. (The accompanying plan of the mine shows the conditions up to Sept. 30th only, in order to get printing done in time for the Annual Meeting.)

The Keewatin formation has been encountered in the westerly part of your mine in both levels, cutting out the veins, and proves to be dipping very uniformly to the east and south, indicating that probably a very productive portion of your property has not yet been reached. The underground workings and surface explorations may now be considered to cover an area of about 12 acres of a total of 40.

Your Directors desire to express their appreciation of the efficiency of the entire staff during the past year, and of the spirit of harmony and enthusiastic co-operation shown in all departments.

The following table shows the work done to date, and the work done during the past year ending October 31st, 1908.

Cross cutting	641 feet.	545 feet.	96 feet.
	Total to Oct. 31, '08.	To Oct. 31, '07.	Done During past year.
Shaft sinking	422 feet.	150 feet.	272 feet.
Drifting..	3756 feet.	1660 feet.	272 feet.
Winzes	94 feet.	00 feet.	94 feet.

Estimate of total rock excavated to Oct. 31st, 1908:

Cross cutting	2,280 tons	(barren ground)	2,280 tons
Drifting	12,980 "		
Stoping	13,680 "		
Open cutting	4,680 "		
Shaft sinking	1,400 "	" "	250 "
Winzes	320 "		
	35,340 "		2,530 "

VIEW OF THE CONIAGES MINE, COBALT, ONT.

Of the above total		35,340 "
Barren rock	2,530 tons	
Mill rock in surface dumps	14,796 "	
Mill rock in stopes	3,950 "	
	21,276 "	21,276 "
Estimate of rock that has been milled		14,064 "

of which there is stocked 4,000 tons of jig tailings with a silver content of about 13 ounces per ton to be recrushed.

From the above amounts the rich ore was hand picked from about 33,000 tons, and 14,064 tons have been concentrated, yielding 297 tons of concentrates.

The total silver produced by this property during the past year is 1,444,229 ounces, making a total to date of 3,444,000 ounces, and a careful estimate of the ore in sight as actually developed by the under-ground workings amounts to thirteen million ounces.

The average price obtained for silver for the past year was 52.3c. per ounce, as against an average price for the previous year of 67.05c. an average difference of 14¾c. per ounce.

Your Company owns the issued capital stock of The Coniagas Reduction Company, Limited, with the exception of six shares, issued to directors to qualify.

The works at Thorold are now handling the product of your mine and are running commercially as regards the production of refined silver and refined white arsenic, and we expect to place refined cobalt oxide and nickel oxide on the market very shortly, thus refining and marketing all the valuable constituents of your Ores by a process which is confidently expected to yield a substantial profit.

The Coniagas Reduction Company, Limited. Dominion Government Charter. Capitalization, $250,000.00; par value of shares, $100.00. Directors: R. W. Leonard, President, St. Catharines, Ont.; Alex. Longwell, Vice-President, Toronto; Milton L. Hersey, Montreal, Que.; W. M. Boulbee, Toronto, Ont.; Welland D. Woodruff, St. Catharines; R. L. Peek, Thorold, Ont.

All of which is respectfully submitted. R. W. Leonard, President and General Manager.

THE CONIAGAS MINES, LIMITED.

After careful examination of the books and vouchers of The Coniagas Mines, Limited, for the 12 months ending Oct. 31st, 1908, I beg to report that I find the books systematically kept, from which the following abstracts are correct. R. Fowlie. Auditor; St. Catharines, Ont., Nov. 17th, 1908.

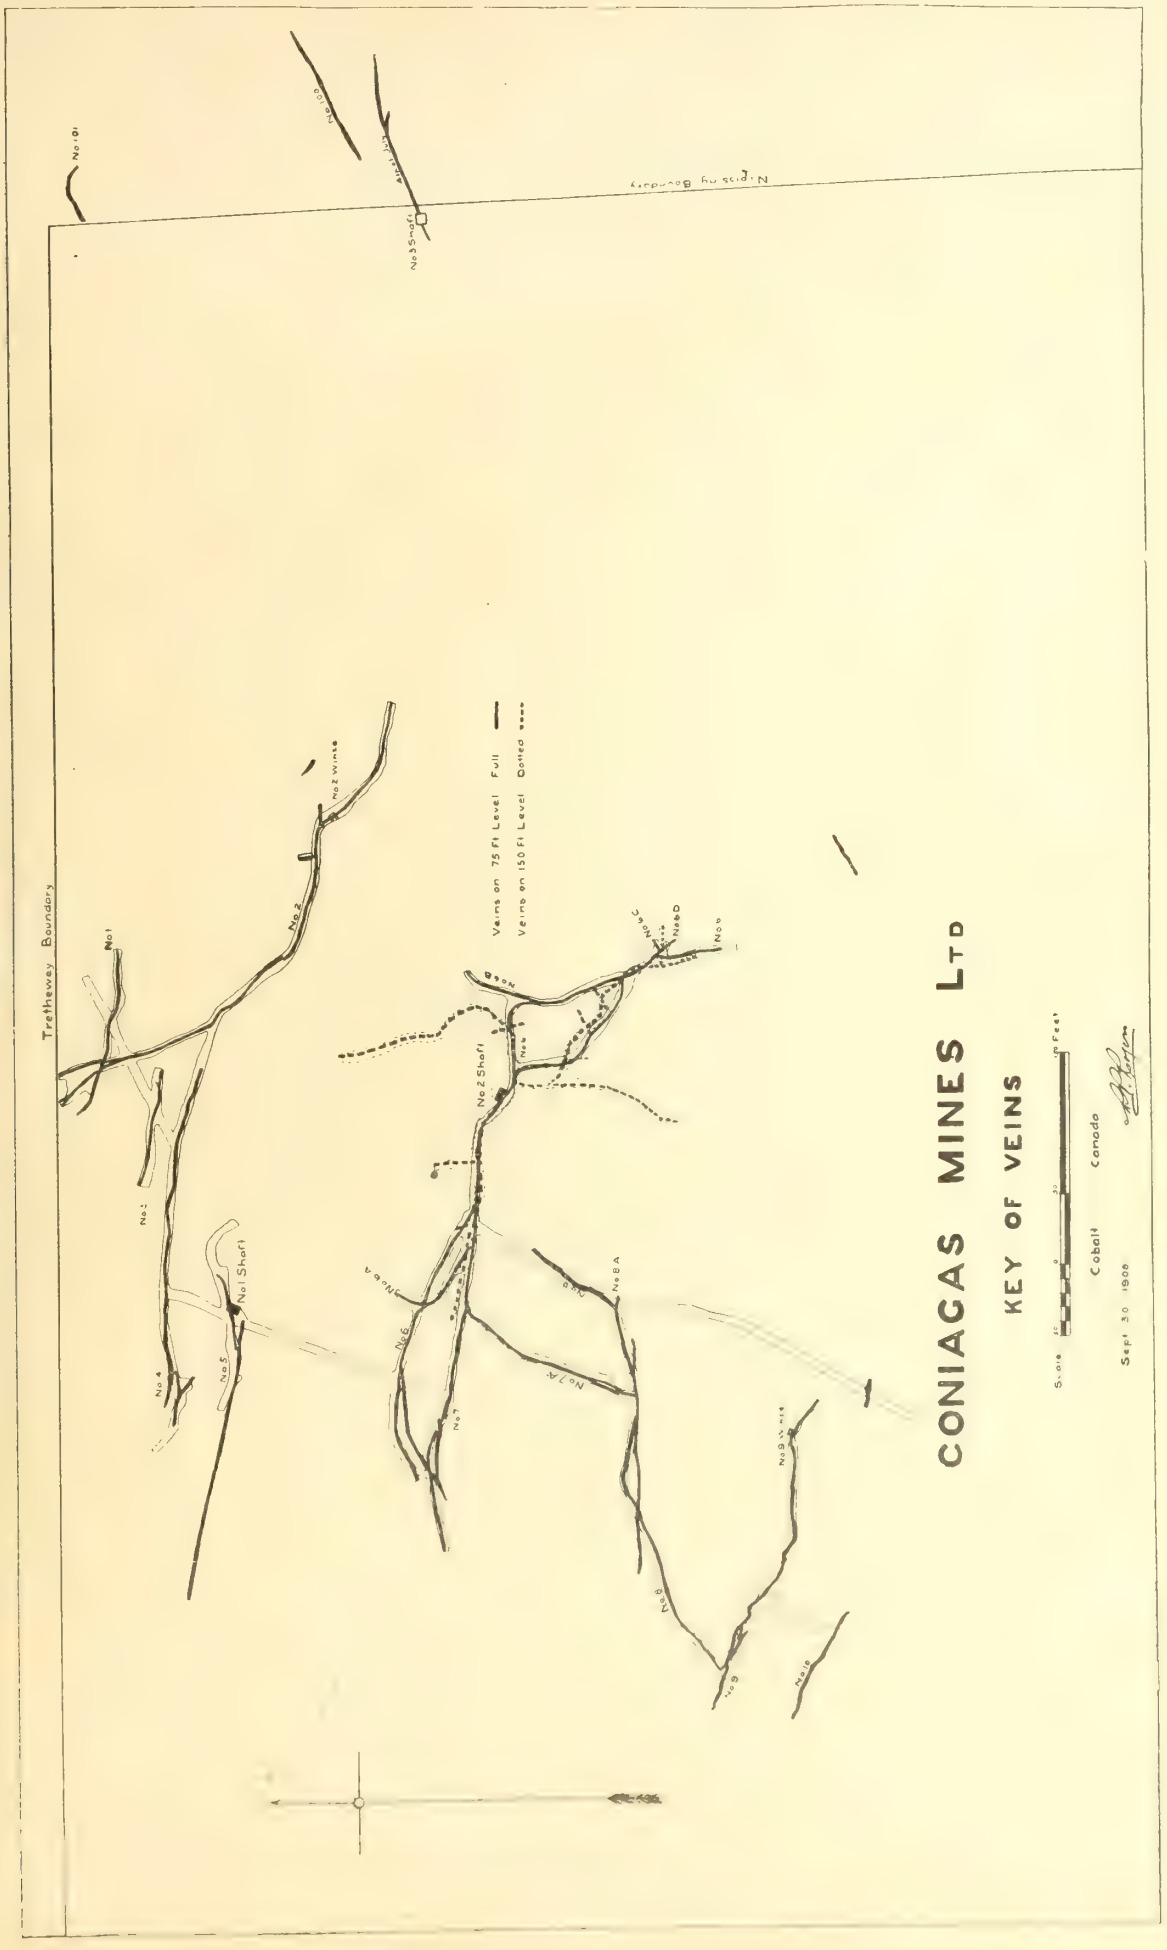
Financial Statement for the Year Ending Oct. 31, 1908.

Assets.

Mines and Minerals	$3,985,700.00
Office equipment	200.00
Machinery and plant	68,237.95
Camps and buildings	82,153.56
Camp equipment	2,502.51
Camp supplies inventory	1,580.52
Coniagas Reduction Co. stock	100,000.00
Accounts Receivable	262.58
Cash on hand and in Bank	173,742.31
Ore in transit	173,993.91
	$4,544,373.34

Liabilities.

Capital stock	$40,000,000.00
Unclaimed wages	45.31
Dividend payable	120,000.00
Accounts payable	107,847.73
Surplus	326,480.30
	$4,554,373.34



Examined and found correct, R. Fowlie, Auditor; J. J. Mackan, Secretary; St. Catharines, Ont., Nov. 17th, 1908.

Working Account.

To Administration and Supervision	$22,360.91

	$766,480.30
By balance, (gain) from Oct. 31st, 1907	$264,762.22
" Mine Profit for year ending Oct. 31st, 1908, as shown in working account	501,718.08
	$766,480.30

Examined and found correct, R. Fowlie, Auditor; J. J. Mackan, Secretary; St. Catharines, Ont., Nov. 17th, 1908.

The annual meeting of the Nova Scotia Silver Cobalt Mining Company, Limited, held at the office of the company, 171 St. James Street, Montreal, was attended by a large number of shareholders.

The financial statement of the company was exceedingly pratifying, in view of the fact that this property is now being developed with due regard to the future shipments of ore.

The consulting engineer of the company, Mr. Benjamin B. Lawrence, explained at some length to the meeting that to make regular shipments of ore it is necessary to get the mine fitted up for the economical handling of the large body of ore known to exist on this property.

The profit for the year on the shipments of ore amounted to	$104.117 04
This does not include a large quantity of screenings ready for shipment, which will be sold this winter, netting the company at least	150.000 00
The second-class ore is also estimated to net the company within the next six months at least	100,000 00
This would make a total of	$354.117 04
For ore extracted during the year at a cost to the company of	103.198 00
Leaving a surplus on ore account of	$250.919 04

The ore body exposed in the mine from the report of our consulting engineer varies from 4 to 8 feet wide, and has been tapped on the lowest level, namely, 165 feet from the surface, where some very rich silver veins hav also been found.

The directors have every reason to believe that dividends on this property will be paid some time next year.

The machinery, buildings, and equipment are considered the best in the camp. The shareholders ought to be congratulated on the future prospects of this property.

The company decided to accept an offer of 65 cents a share for the balance of the treasury stock.

The following directors were re-elected: D. M. Steindler, president; Mortimer B. Davis, Vice President; Jacob A. Jacobs, Secretary-Treasurer; A. M. Bilsky, Managing Director; A. M. Reaper, Director.

STATISTICS AND RETURNS.

The official bulletin of the Antwerp bureau of commerce, which undertakes annually the task of compiling the coal output statistics of the entire world, has just announced the following figures for the year 1906, the last for which definite results have been obtainable. The world's total coal out-put for 1906 amounts to 893,249,557 tons, as against 844,194,217 tons in 1905. Ten years ago, in 1896, the grand total was 546,742,207 tons, in 1886 it was 303,207,780 tons, in 1870 it was 203,321,112 tons, and in 1850 only 89,881,357 tons—a striking record of the progress of the world's industries. The first place as a coal-producing country is held by the United States of America, whose record for 1906 was 375,397,000 tons, more than 42 per cent. of the total. This place it has held since 1899. The second place upon the list is held by Breat Britain, with a record of 251,050,000 tons, over 28 per cent. of the total. Germany comes next, with 136,480,000 tons, about 15 per cent of the tota,l and France makes a very bad fourth, with 34,313,000 tons. A very interesting development is shown by Japan and Canada. Japan appears to have increased her production from 1,243,000 tons in 1905, to 12,500,000 tons in 1906, while the Canadian production in 1906 amounted to 9,916,000 tons, or five times as much as it was twenty years ago.

DOMINION COAL SHIPMENTS.

The Dominion Coal Co.'s output for November was 244,304 tons; shipments, 233,558 tons.

Shipments from the collieries of the Cumberland Railway and Coal Company, for the month of November, were 26,709 tons.

BOUNDARY SHIPMENTS.

NOVA SCOTIA STEEL OUTPUT.

Nova Scotia Steel's outputs for November were: Coal, 54,400 tons; pig iron, 4,580 tons; steel, 3,600 tons.

The output of the Crow's Nest Coal Company collieries for the week ending December 4 was 18,457 tons a day average of 3,076 tons. Week ending December 6, 1907, 23,212 tons, a daily average of 3,869 tons.

The output of the Crow's Nest Coal Company collieries for the week ending November 27 was 17,728 tons; daily average, 2,956 tons; week ending November 29, 1907, 21,800 tons; a daily average of 3,637 tons; week ending November 30, 1906, 13,736 tons, a daily average of 2,289 tons.

Shipments of ore from the Cobalt camp last week slightly exceeded the previous week, when they amounted to 635 tons. Last week they amounted to 700 tons.

The total shipments for the week were 1,401,960 lbs., or 700 tons, and the total for the year so far is 42,816,550 lbs., or 21,481 tons. Details follow:—

In the manufacture of alcohol from peat, a Danish company, with one experimental plant in Denmark and one in France, has found the cost to be about one-fourth of that made from potatoes. In the process of manufacture, the cellulose or fiber of the peat is converted by sulphuric acid into a soluble carbohydrate, and this is fermented by a special yeast.

Amatite ROOFING

PAINTING a roof is work. Buying the paint is expense. Both are needless if your roof is Amatite.

When you finish laying Amatite, take away your ladder, pick up your hammer and knife, go away and leave the roof to take care of itself. A few years later you may go back and look at it if you care to, but it won't be necessary, and there won't be anything to do.

This is due to the fact that Amatite has a *real mineral surface*—a surface that is too strong to need protection—too durable to require painting.

If you buy one of the smooth surfaced roofings you will have to paint it every two or three years to keep it from leaking. In fact, such roofs depend on the paint almost entirely for their waterproofing qualities.

Amatite on the other hand depends for its waterproofing upon double layers of Coal Tar Pitch,—the greatest known enemy to water.

Amatite comes in rolls of 110 square feet ready to lay. No special tools are required, and anyone can lay it properly.

A Sample of Amatite will be forwarded free on request. Send for it and see how much better it is than the kind which requires painting to keep tight.

Some Books of interest on Mining to be had from the Book Department of the Canadian Mining Journal, Toronto, Ont.

The Copper Mines of Lake Superior. By T. A. Rickard. An attractive volume of 165 pages, handsomely illustrated. The present work consists of a group of interesting articles in a revised and amplified form, which were originally published in the columns of The Engineering and Mining Journal during the latter part of 1904. Octavo, cloth. Price, $1.00.

The Chemistry of Cyanide Solutions Resulting from the Treatment of Ores. By J. C. Clennell. Price, 2.50.

Across the San Juan Mountains. By T. A. Rickard. A graphic description of a picturesque ride of 400 miles on horseback through the San Juan Mountains in South-western Colorado. The work is written in vigorous and buoyant style, and the information contained therein, while appealing specifically to the geologist, prospector, and mining engineer, will also prove of great interest and enjoyment to the general reader. Small quarto, cloth, ornamental covers and profusely illustrated. Price, $1.00.

Ore Deposits. A discussion republished from the Engineering and Mining Journal, containing the recent contributions on the origin of ores. By S. F. Emmons, W. H. Weed, F. L. Ransome, C. R. Van Hise, T. A. Rickard, and C. W. Purington. The matter originally published has been revised and amplified. A review of the subject by the Editor of the Engineering and Mining Journal is added. It is an up-to-date discussion of a subject which is of great interest to mining men. The book contains 100 pages. Cloth. $1.00.

Mineral Resources of Canada. An illustrated handbook giving a brief outline of the economic minerals of Canada, and sketching the mineral resources of each province. The book contains 140 pages, 32 color engravings of the most important minerals. The latest mineral Resource Map of the Dominion, showing the chief mineral deposits, is also included. No such work has been attempted in Canada before. This volume should be in the hands of every one interested in the mining industry. The price of this volume is extremely moderate. $1.00.

Minerals and How They Occur. By Willet G. Miller, Provincial Geologist, a volume of 250 pages, illustrated. This book is especially adapted to the prospector for minerals, as he must have a knowledge of mineralogy before he can properly understand the character of rocks and the effects which are produced on them by atmospheric and other agencies. If you are a prospector this is the work for you. Price, $1.00.

The Sampling and Estimation of Ore in a Mine. By T. A. Rickard. Sampling and mine valuation are eminently practical subjects, and in this work they are handled in detail by engineers and experts of the first rank, who have had world-wide experience in these matters. To students, mine directors, mining engineers, mine investors, and engineers generally, this volume will be found extremely useful. Octavo cloth, profusely illustrated. Price, $2.00.

Rocks and Rock Minerals. By L. V. Pirsson, Professor of Geology in Yale University, 414 pages, 74 figures, 36 full-page half-tone plates. Not all mining men have an intimate knowledge of petrology, or the science of rocks. Even those who have had the advantage of a college course find that only a small residue of what they learned adheres to them. Most text-books on the subjects are cast into forms that repel the lay reader. Hence it is not easy for the beginner to acquire the rudiments of the science. "Rocks and Rock Minerals" is an attempt to present the outlines of petrology in such a way as to give an intelligent idea of the subject to readers quite unacquainted with the microscopic standpoint. Rocks and rock minerals are dealt with entirely from a megascopic, or practical outdoors, point of view. The book before us attains the desired object of giving the reader a knowledge of rocks and rock minerals without recourse to the microscope. It is a very fair introduction to the study of geology generally. Part III., in which igneous, stratified, and metamorphic rocks are described, is an excellent treatise in itself. Simplicity is the keynote of the book. Cloth. Price, $2.50 net.

A History of Cobalt. During the summer of 1907 the Canadian Mining Journal published a beautiful illustrated souvenir volume. Included in this volume is a history of the early days of Cobalt. An excellent map of the district accompanies the book. Price, $1.00.

The Electric Furnace. By Alfred Stansfield, D.Sc., A.R.S.M., Professor of Metallurgy, McGill University. There has long been need of a good book on electric furnaces. The increased importance of the subject and the great value to metallurgy makes this book most timely. 211 pages (illustrated) 6 x 9 inches. Price, $2.00.

Simple Mine Accounting. By David Wallace. A neat compact description of the simple methods of keeping mine accounts. Mr. Wallace is an expert mine accountant and in this book he outlines briefly and simply the kind of accounts and records which a small mine should keep. 64 pages, 6 x 9 inches, with bookkeeping forms. Price, $1.00.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

THE OFFICIAL MINING DIRECTORY OF MEXICO. 1908-1909

CALLE DEL ELISEO, 37, MEXICO, D. F.

EDITORS: JOHN R. SOUTHWORTH, F.R.C.S. and PERCY C. HOLMES.

"The Official Mining Directory of Mexico" is the 10th volume of the series of works, devoted to the propagation of knowledge concerning the resources of M exico, which has been issued from these effices under the authorization of the Mexican Government, each co py being duly impressed with the Federal Seal of the United States of Mexico.

The contents of the work comprise:

Alphabetically listed descriptions of over 1,500 M ining companies operating over 7,000 mining properties in Mexico. Only such companies as employ more than 20 men, or use power other than animal power, are listed.

The data given, in respect to these companies, is exemplified in the specimen shown on this sheet. It includes name of company, home office address, mine o ffice address, president, secretary, treasurer, directors, manager, superintendent, subordinate staff, where and when incorporated, capitalization, issued stock, par value of shares, additional financial data, names of m ines, number of claims, product, description of ore, description of geological formation, kind of power used , number of horsepower used, description of mine workings, capacity of treatment plant, cyanide plant, smelter , etc., number and weight of stamps, number of grinding mills, number of tube mills, number of concentrators, number of men employed, contemplated improvements, general remarks.

The volume is illustrated by over 200 photographs and maps, showing the leading mines, mills, smelters, and camps in the Republic.

Tables of utility to mining men, shippers and inv estors are given.

A Spanish-English glossary of Mining Terms make s the translation of letters from Mexican miners possible, where a dictionary would be valueless.

Preliminary to the actual directory, there are spec ial articles, written by competent Mexican and foreign authorities, on:

"The History of Mining in Mexico."

"Number and Geographical Distribution of Mines in Mexico."

"Foreign Investments in Mexican Mining Securiti es."

"Progress of the Metallurgy of Gold and Silver in Mexico."

"The Mexican Mining Chamber."

"The Mexican Mining Laws."

"The International Bureau of American Republics ."

The edition presented to your notice is in English, and contains 280 pages, measuring 13 inches by 10 inches, bound in chocolate colored cloth, with the title in gold lettering on side and back. Type and paper are of the finest quality. Price, $5.00, U.S. Cey., £1 1s. 0d. stg., M22., $10.00, Mex. Cey., Frs. 25, postpaid.

Copies of this excellent work may be had from the Book Department of Canaadian Mining Journal, Toronto

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of specimens at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Fernie, British Columbia

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905. Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 500,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

CHAS. SIMISTER, General Superintendent.

J. D. HURD, General Manager.

WHY IS IT

THAT SALES OF

MORTON'S

"BC"

Drill Steel

ARE INCREASING EVERY DAY?
MUST BE IT IS BETTER MATERIAL,

Gives Best Satisfaction

AND THE DRILL

Lasts Longer.

COULD ANYONE EXPECT MORE?

IN STOCK WITH

DOMINION OF CANADA

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY, **Deputy of the Minister of the Interior**

OFFICE AND WORKS :
St. Patrick St., Montreal

MANUFACTURERS

of Steel Castings of all kinds, Springs, Frogs and Diamond Crossings

We make a specialty of

Manganese Steel Castings

for Mining purposes.

AGENTS FOR

THOMAS FIRTH & SONS, Limited

"Speedicut" high speed steel, tool steel, axe steel, saw steel, files, etc. A large stock carried in our Montreal warehouse.

Also Agents for Barrow, Haematite Steel Company, of Barrow in Furness, England.

Steel Rails of all kinds, Fish Plates, etc.

RAMPART CEMENT

Perfectly Sound. Never swells or bursts.

Reliable for all purposes for which hydraulic cement is used.

Fineness 92 per cent. through a 200 mesh sieve.

Strength up to standard specifications, and permanent.

Used by the leading Mining Companies of the Maritime Provinces.
